Categorizing Percepts: Vantage Theory

K Allan, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Vantage theory (VT) is a theory of cognitive categorization in terms of point of view or 'vantage.' The underlying assumption is that categorization reflects human needs and motives. VT was created by the late Robert E. MacLaury as a way of explaining the meanings and development of color terms across languages when he found prototype theory and fuzzy-set logic inadequate to the task (see MacLaury 1986, 1987, 1991, 1995, 1997, 2002). VT explains

- how people construct categories by analogy to the way they form points of view in space–time;
- how categories are organized;
- how categories divide; and
- the relations between categories.

In VT, cognition consists of selective attention to perception. To form a category, selected perceptions and reciprocal emphases on similarity and difference must be integrated in a principled way. A vantage is a point of view constructed by analogy to physical experience as though it were one or more 'space–motion coordinates' on a spatial terrain. Reminiscent of gestalt theory is MacLaury's claim that a category is the sum of its coordinates, plus their arrangement into one or more vantages by selective emphasis. "The maker of the category, in effect, names the ways he constructs it rather than the set of its components as detached from himself" (1997: 153).

The categorizer's perspectives can be illustrated by an ornithologist 'zooming in' to see a mallard among the ducks on a lake, or alternatively 'zooming out' to see the assembled mallards, widgeon, and pintails as ducks. The mallard is the 'fixed coordinate'; the rest a 'mobile coordinate.' In both views, there is a pair of coordinates that we can loosely differentiate as 'species' and 'genus.'

CONCENTRATION		COORDINATES		BEHAVIOR
Zoom in		Fixed	Mobile	Focus and range
↓	Level 1	Red	S	Red focus, breadth of range
↓			↙	
↓	Level 2	S	Yellow	Warm range
↓			↙	
	Level 3	Yellow	D	Margin of range
Synopsis: Yellow is more similar to red than it is different				

Figure 1 Red focus in the composite 'warm' category; cf. MacLaury (1997: 145).

Imagine mapping warm-category colors (red, yellow) in an array of colored blocks representing the entire color spectrum. If each of the terms 'red' and 'yellow' is mapped differently, there is a single vantage. If there is coextensive mapping (evidence of a composite 'warm' color) with red focus [*see* **Color Terms**], red will dominate at the primary level of concentration, Level 1 in Figure 1, and attention is on 'similarity,' S, as the mobile coordinate. At Level 2 concentration, attention to the mobile coordinate yellow notes its similarity to red (as a warm color). At Level 3, there is attention to D, the 'difference' of fixed coordinate yellow from red. Here, yellow is recessive. Thus does VT model the dominant–recessive pattern of coextensive naming. The dominant vantage includes reinforced attention to similarity; the recessive vantage reinforces attention to difference. Thus, a category is composed of

- selected perceptions;
- reciprocal and mutable emphases on similarity and difference; and
- at least one arrangement of these coordinates into levels of concentration—which is the vantage.

VT has been applied to many cognitive fields: the category of person in 16th century Aztec; literacy choices for Yaquis in Arizona; choice of orthography in Japan; semantic extensions in English, French, Spanish, and Zapotec; lexical choices in French; varieties of Japanese women's speech; terms of address in Japanese; the process of argumentation; and foreign language learning.

Principles of Organization

Theories of the organization of conceptual knowledge in the brain can be distinguished according to their underlying principles. One class of theories, based on the neural structure principle, assumes that the organization of conceptual knowledge is governed by representational constraints internal to the brain itself. Two types of neural constraints have been invoked: modality-specificity and domain-specificity. The second class of theories, based on the correlated structure principle, assumes that the organization of conceptual knowledge in the brain is a reflection of the statistical co-occurrence of object properties in the world. Neuropsychological evidence, and more recently findings from functional neuroimaging, have figured centrally in attempts to evaluate extant theories of the organization of conceptual knowledge. Here we outline the main theoretical perspectives as well as the empirical phenomena that have been used to inform these perspectives.

Modality-Specific Hypotheses

The first class of theories based on the neural structure principle assumes that the principal determinant of the organization of conceptual knowledge is the sensory-motor modality (e.g., visual, motor, verbal) through which the information was acquired or is typically processed. For instance, the knowledge that hammers are shaped like a T would be stored in a semantic subsystem dedicated to representing the visual structure of objects, while the information that hammers are used to pound nails would be represented in a semantic subsystem dedicated to functional knowledge of objects. There have been many proposals based on the modality-specific assumption (Beauvois, 1982; Warrington and McCarthy, 1983, 1987; Warrington and Shallice, 1984; Allport, 1985; Martin *et al.*, 2000; Humphreys and Forde, 2001; Barsalou *et al.*, 2003; Cree and McRae, 2003; Crutch and Warrington, 2003; Gallese and Lakoff, in press). One way to distinguish between these proposals concerns whether, and to what extent, conceptual knowledge is assumed to be represented independently of sensory-motor processes. At one extreme are theories that assume conceptual content reduces to (i.e., actually **is**) sensory-motor content (e.g., Allport, 1985; Pulvermuller, 2001; Barsalou *et al.*, 2003; Gallese and Lakoff, in press). Central to such proposals is the notion of simulation, or the automatic reactivation of sensory-motor information in the course of conceptual processing. Toward the other end of the continuum are modality-based hypotheses of the organization of conceptual knowledge that assume that sensory-motor systems may be damaged without compromising the integrity of conceptual knowledge (Martin *et al.*, 2000; Plaut, 2002; Crutch and Warrington, 2003; for discussion, see Mahon and Caramazza, in press).

Domain-Specific Hypotheses

A second class of proposals based on the neural structure principle assumes that the principal determinant of the organization of conceptual knowledge is semantic category (e.g., Gelman, 1990; Carey and Spelke, 1994; Caramazza and Shelton, 1998; Kanwisher, 2000). For instance, in this view, it may be argued that conceptual knowledge of conspecifics and conceptual knowledge of animals are represented and processed by functionally dissociable processes/systems. Crucially, in this view, the first order principle of organization of conceptual processing is semantic category and not the modality through which that information is typically processed. One proposal along these lines, the Domain-Specific Hypothesis (Caramazza and Shelton, 1998), argues that conceptual knowledge is organized by specialized (and functionally dissociable) neural

Principles of Organization

Theories of the organization of conceptual knowledge in the brain can be distinguished according to their underlying principles. One class of theories, based on the neural structure principle, assumes that the organization of conceptual knowledge is governed by representational constraints internal to the brain itself. Two types of neural constraints have been invoked: modality-specificity and domain-specificity. The second class of theories, based on the correlated structure principle, assumes that the organization of conceptual knowledge in the brain is a reflection of the statistical co-occurrence of object properties in the world. Neuropsychological evidence, and more recently findings from functional neuroimaging, have figured centrally in attempts to evaluate extant theories of the organization of conceptual knowledge. Here we outline the main theoretical perspectives as well as the empirical phenomena that have been used to inform these perspectives.

Modality-Specific Hypotheses

The first class of theories based on the neural structure principle assumes that the principal determinant of the organization of conceptual knowledge is the sensory-motor modality (e.g., visual, motor, verbal) through which the information was acquired or is typically processed. For instance, the knowledge that hammers are shaped like a T would be stored in a semantic subsystem dedicated to representing the visual structure of objects, while the information that hammers are used to pound nails would be represented in a semantic subsystem dedicated to functional knowledge of objects. There have been many proposals based on the modality-specific assumption (Beauvois, 1982; Warrington and McCarthy, 1983, 1987; Warrington and Shallice, 1984; Allport, 1985; Martin *et al.*, 2000; Humphreys and Forde, 2001; Barsalou *et al.*, 2003; Cree and McRae, 2003; Crutch and Warrington, 2003; Gallese and Lakoff, in press). One way to distinguish between these proposals concerns whether, and to what extent, conceptual knowledge is assumed to be represented independently of sensory-motor processes. At one extreme are theories that assume conceptual content reduces to (i.e., actually **is**) sensory-motor content (e.g., Allport, 1985; Pulvermuller, 2001; Barsalou *et al.*, 2003; Gallese and Lakoff, in press). Central to such proposals is the notion of simulation, or the automatic reactivation of sensory-motor information in the course of conceptual processing. Toward the other end of the continuum are modality-based hypotheses of the organization of conceptual knowledge that assume that sensory-motor systems may be damaged without compromising the integrity of conceptual knowledge (Martin *et al.*, 2000; Plaut, 2002; Crutch and Warrington, 2003; for discussion, see Mahon and Caramazza, in press).

Domain-Specific Hypotheses

A second class of proposals based on the neural structure principle assumes that the principal determinant of the organization of conceptual knowledge is semantic category (e.g., Gelman, 1990; Carey and Spelke, 1994; Caramazza and Shelton, 1998; Kanwisher, 2000). For instance, in this view, it may be argued that conceptual knowledge of conspecifics and conceptual knowledge of animals are represented and processed by functionally dissociable processes/systems. Crucially, in this view, the first order principle of organization of conceptual processing is semantic category and not the modality through which that information is typically processed. One proposal along these lines, the Domain-Specific Hypothesis (Caramazza and Shelton, 1998), argues that conceptual knowledge is organized by specialized (and functionally dissociable) neural

circuits innately determined to the conceptual processing of different categories of objects. However, not all Domain-Specific theories assume that the organization of the adult semantic system is driven by innate parameters (e.g., Kanwisher, 2000).

Feature-Based Hypotheses

The class of hypotheses based on the correlated structure principle has focused on articulating the structure of semantic memory at the level of semantic features. There are many and sometimes diverging proposals along these lines; common to all of them is the assumption that the relative susceptibility to impairment (under conditions of neurological damage) of different concepts is a function of statistical properties of the semantic features that comprise those concepts. For instance, on some models, the degree to which features are shared by a number of concepts is contrasted with their relative distinctiveness (Devlin *et al.,* 1998; Garrard *et al.,* 2001; Tyler and Moss, 2001). Another dimension that is introduced by some theorists concerns dynamical properties of damage in the system; for instance, Tyler and Moss assume that features that are more correlated with other features will be more resistant to damage, due to greater reciprocal activation (or support) from those features with which they are correlated (but see Caramazza *et al.,* 1990). Distinctive features, on the other hand, will not receive as much reciprocal support, and will thus be more susceptible to damage. More recently, theorists have expanded on the original proposal of Tyler and colleagues, adding dimensions such as familiarity, typicality, and relevance (e.g., Cree and McRae, 2003; Sartori and Lombardi, 2004). Feature-based models of semantic memory have in general emphasized an empirical, bottom up, approach to modeling the organization of semantic memory, usually drawing on feature generation tasks (e.g., Garrard *et al.,* 2001; Tyler and Moss, 2001; Cree and McRae, 2003; Sartori and Lombardi, 2004). For this reason, feature-based models have been useful in generating hypotheses about the types of parameters that may contribute to the organization of conceptual knowledge.

Clues from Cognitive Neuropsychology

Neuropsychological studies of patients with semantic impairments have figured centrally in developing and evaluating the hypotheses outlined above. Of particular importance has been a clinical profile described as category-specific semantic deficit. Patients with category-specific semantic deficits present with disproportionate or even selective difficulty for conceptual knowledge of stimuli from one semantic category compared to other semantic categories. For instance, the reports of category-specific impairment by Warrington and her collaborators (e.g., Warrington and McCarthy, 1983, 1987; Warrington and Shallice, 1984) documented patients who were impaired for living things compared to nonliving things, or the reverse: greater difficulty with nonliving things than living things. Since those seminal reports, the phenomenon of category-specific semantic deficit has been documented by a number of investigators (for recent reviews of the clinical evidence, see Humphreys and Forde, 2001; Tyler and Moss, 2001; Capitani *et al.,* 2003).

The clinical profile of category-specific semantic deficits is in itself quite remarkable, and can be striking. Consider some aspects of the following case of category-specific semantic deficit for living animate things. Patient EW (Caramazza and Shelton, 1998) was 41% correct (7/16) for naming pictures of animals but was in the normal range for naming pictures of non-animals (e.g., artifacts, fruit/vegetables) when the pictures from the different semantic categories were matched jointly for familiarity and visual complexity. EW was also severely impaired for animals (60%; 36/60 correct) in a task in which the patient was asked to decide, yes or no, whether the depicted stimulus was a real object or not. In contrast, EW performed within the normal range for making the same types of judgments about non-animals. On another task, EW was asked to decide whether a given attribute was true of a given item (e.g., Is it true that eagles lay eggs?). EW was severely impaired for attributes pertaining to animals (65% correct) but within the normal range for non-animals. EW was equivalently impaired for both visual/perceptual and functional/associative knowledge of living things (65% correct for both types of knowledge) but was within the normal range for both types of knowledge for non-animals.

The phenomenon of category-specific semantic deficits frames what has proven to be a rich question: How could the conceptual system be organized such that various conditions of damage can give rise to conceptual impairments that disproportionately affect specific semantic categories? There is emerging consensus that any viable answer to this question must be able to account for the following three facts (for discussion, see Caramazza and Shelton, 1998; Tyler and Moss, 2001; Capitani *et al.,* 2003; Cree and McRae, 2003; Samson and Pillon, 2003).

Fact I: The grain of the phenomenon: Patients can be disproportionately impaired for either living animate things (i.e., animals) compared to living inanimate things (i.e., fruit/vegetables (e.g., Hart and

Gordon, 1992; Caramazza and Shelton, 1998) or living inanimate things compared to living animate things (e.g., Hart *et al.,* 1985; Crutch and Warrington, 2003; Samson and Pillon, 2003). Patients can also be impaired for nonliving things compared to living things (Hillis and Caramazza, 1991).

Fact II: The profile of the phenomenon: Category-specific semantic deficits are not associated with disproportionate impairments for modalities or types of information (e.g., Caramazza and Shelton, 1998; Laiacona and Capitani, 2001; Farah and Rabinowitz, 2003; Samson and Pillon, 2003). Conversely, disproportionate impairments for modalities or types of information are not necessarily associated with category-specific semantic deficits (e.g., Lambon-Ralph *et al.,*1998; Miceli *et al.,* 2001).

Fact III: The severity of overall impairment: The direction of category-specific semantic deficits (i.e., living things worse than nonliving things, or vice versa) is not related to the overall severity of semantic impairment (Garrard *et al.,* 1998; Zannino *et al.,* 2002).

Explaining Category-Specific Semantic Deficits

Most of the empirical and theoretical work in category-specific semantic deficits has been driven by an attempt to evaluate a theoretical proposal first advanced by Warrington, Shallice, and McCarthy (Warrington and McCarthy, 1983, 1987; Warrington and Shallice, 1984): the Sensory/Functional Theory. The Sensory/Functional Theory is an extension of the modality-specific semantic hypothesis (Beauvois, 1982) discussed above. In addition to assuming that the semantic system is functionally organized by modality or type of information, the Sensory/Functional Theory assumes that the recognition/identification of items from different semantic categories (e.g., living things compared to nonliving things) differentially depends on different modality-specific semantic subsystems. In general, Sensory/Functional theories assume that the ability to identify/recognize living things differentially depends on visual/perceptual knowledge, while the ability to identify/recognize nonliving things differentially depends on functional/associative knowledge (for data and/or discussion of the assumption that different types or modalities of information are differentially important for different semantic categories, see Farah and McClelland, 1991; Caramazza and Shelton, 1998; Garrard *et al.,* 2001; Tyler and Moss, 2001; Cree and McRae, 2003). There are several versions of the Sensory/Functional Theory, each of which has emphasized a different correspondence between the type or modality of information and the category of items that differentially depends on that type of information. For instance, it has been proposed that color information is more important for fruit/vegetables than animals (e.g., Humphreys and Forde, 2001; Cree and McRae, 2003; Crutch and Warrington, 2003) while biological motion information is more important for animals than for fruit/vegetables (e.g., Cree and McRae, 2003). Another version of the Sensory/Functional Theory (Humphreys and Forde, 2001) holds that there is greater perceptual crowding (due to greater perceptual overlap) at a modality-specific input level for living things than for nonliving things. Thus, damage to this visual modality-specific input system will disproportionately affect processing of living things compared to nonliving things (see also Tranel *et al.,* 1997; Dixon, 2000; Laws *et al.,* 2002).

Common to theories based on the Sensory/Functional Assumption is that at least some category-specific semantic deficits can be explained by assuming damage to the modality or type of information upon which recognition/identification of items from the impaired category differentially depends (for discussion see Humphreys and Forde, 2001). Other authors have argued that the fact that category-specific semantic deficits are not necessarily associated with deficits to a modality or type of knowledge (see Fact II above) indicates that the phenomenon does not provide support for Sensory/Functional theories (for discussion, see Caramazza and Shelton, 1998; Tyler and Moss, 2001; Capitani *et al.,* 2003; Cree and McRae, 2003; Samson and Pillon, 2003).

Caramazza and Shelton (1998) argued for a Domain-Specific interpretation of category-specific semantic deficits that emphasized the hypothesis that the grain of category-specific semantic deficits will be restricted to a limited set of categories. Specifically, because the Domain-Specific Hypothesis (Caramazza and Shelton, 1998) assumes that the organization of conceptual and perceptual processing is determined by innate constraints, the plausible categories of category-specific semantic impairment are 'animals,' 'fruit/vegetables,' 'conspecifics,' and possibly tools. Recent discussion of this proposal (Caramazza and Mahon, in press; see also Shelton *et al.,* 1998) has capitalized on using the category 'conspecifics' as a test case. Consistent with expectations that follow from the Domain-Specific Hypothesis, patients have been reported who are relatively impaired for knowledge of conspecifics but not for animals or objects (e.g., Kay and Hanley, 1999; Miceli *et al.,* 2000) as well as the reverse: equivalent impairment for animals and objects but spared knowledge of conspecifics (Thompson *et al.,* 2004). Thus, the domain of conspecifics can be spared or impaired independently of both objects and other

living things, and importantly, an impairment for conspecifics is not necessarily associated with a general impairment for living things compared to nonliving things.

Another line of research has sought an account of category-specific semantic deficits in terms of feature-based models of semantic memory organization. For instance, the Organized Unitary Content Hypothesis (OUCH) (Caramazza *et al.,* 1990) makes two principal assumptions. First, conceptual features corresponding to object properties that often co-occur will be stored close together in semantic space; and second, focal brain damage can give rise to category-specific semantic deficits either because the conceptual knowledge corresponding to objects with similar properties is stored in adjacent neural areas, or because damage to a given property will propagate damage to highly correlated properties. While the original OUCH model is not inconsistent with the currently available data from category-specific semantic deficits, it is too unconstrained to provide a principled answer to the question of *why* the various facts are as they are.

Other feature-based models have emphasized the differential susceptibility to impairment of different types of semantic features. These models often assume random (or diffuse) damage to a conceptual system that is not organized by modality or object domain. For instance, in order to account for category-specific semantic deficits, the semantic memory model advanced by Tyler and Moss (2001) makes three assumptions bearing on the relative susceptibility to impairment of different classes of semantic features: (a) Living things have more shared features than nonliving things, or put differently, nonliving things have more distinctive/informative features than living things; (b) For living things, biological function information is highly correlated with shared perceptual properties (e.g., can see/has eyes). For artifacts, function information is highly correlated with distinctive perceptual properties (e.g., used for spearing/has tines). (c) Features that are highly correlated with other features will be more resistant to damage than features that are not highly correlated (see also Devlin *et al.,* 1998; Garrard *et al.,* 2001; Cree and McRae, 2003). This proposal, termed the Conceptual Structure Account, predicts that a disproportionate deficit for living things will be observed when damage is relatively mild, while a disproportionate deficit for nonliving things will only arise when damage is so severe that all that is left in the system are the highly correlated shared perceptual and function features of living things. Recent work investigating the central prediction of the theory through cross sectional analyses of patients at varying stages of Alzheimer's disease has not found support for this prediction (Garrard *et al.,* 1998; Zannino *et al.,* 2002).

Clues from Functional Neuroimaging

Increasingly, the neuropsychological approach is being complemented by functional neuroimaging studies of category-specificity. There is a large body of evidence from functional neuroimaging that demonstrates differentiation by semantic domain within modality-specific systems specialized for processing object form and object-associated motion. Specifically, within the ventral object processing system, areas on the inferior surface of the temporal lobes process object-associated form and texture, while areas on the lateral surfaces of the temporal lobes process object-associated movement (Kourtzi and Kanwisher, 2000; Beauchamp *et al.,* 2002, 2003). Within both form/texture- and motion-specific areas of the ventral object processing system, there is differentiation by semantic category. On the inferior surface of the temporal lobe (e.g., fusiform gyrus), more lateral areas are differentially involved in the processing of living things, while more medial regions are differentially involved in the processing of nonliving things. Furthermore, human face stimuli, in comparison to non-face stimuli (including animals without faces), differentially activate distinct regions of the inferior temporal cortex (Kanwisher *et al.,* 1999). On the lateral surface of the temporal lobes, more superior regions (e.g., superior temporal sulcus) are differentially involved in the processing of motion associated with living things, while more inferior regions (e.g., middle temporal gyrus) are differentially involved in the processing of motion associated with nonliving things (for review, see Kanwisher, 2000; Martin and Chao, 2001; Beauchamp *et al.,* 2002, 2003; Bookheimer, 2002; Caramazza and Mahon, 2003, in press).

All of the theoretical frameworks outlined above have been applied to the data from functional neuroimaging. One widely received view, the Sensory/Motor Theory, developed by Martin, Wiggs, Ungerleider, and Haxby (1996; see also Martin *et al.,* 2000) assumes that conceptual knowledge of different categories of objects is stored close to the modality- specific input/output areas that are active when we learn about and interact with those objects. Other authors have interpreted these patterns of activation within a Domain-Specific Framework (e.g., Kanwisher, 2000; Caramazza and Mahon, 2003, in press), while still others have interpreted these findings within a distributed semantic memory model that emphasizes experience-dependent and/or feature-based properties of concepts (e.g., Tarr and Gauthier, 2000; Levy *et al.,*

2001; Martin and Chao, 2001; Bookheimer, 2002; Devlin *et al.,* 2002). Regardless of what the correct interpretation of these functional neuroimaging data turns out to be, they suggest a theoretical approach in which multiple dimensions of organization can be distinguished. In particular, whether the category-specific foci of activation are interpreted within the Domain-Specific Framework or within a feature-based framework, these data suggest the inference that the organization of conceptual knowledge in the cortex is driven both by the type or modality of the information as well as its content-defined semantic category.

Conclusion

The three proposals that we have reviewed (the Sensory/Functional Theory, the Domain-Specific Hypothesis, and the Conceptual Structure Account) are contrary hypotheses of the causes of category-specific semantic deficits. However, the individual assumptions that comprise each account are not necessarily mutually contrary as proposals about the organization of semantic memory. In this context, it is important to note that each of the hypotheses discussed above makes assumptions at a different level in a hierarchy of questions about the organization of conceptual knowledge. At the broadest level is the question of whether or not conceptual knowledge is organized by Domain-Specific constraints. The second question is whether conceptual knowledge is represented in modality-specific semantic stores specialized for processing/storing a specific type of information, or is represented in an amodal, unitary system. The third level in this hierarchy of questions concerns the organization of conceptual knowledge within any given object domain (and/or modality-specific semantic store): the principles invoked by feature-based models may prove useful for articulating answers to this question (for further discussion of the various levels at which specific hypotheses have been articulated, see Caramazza and Mahon, 2003).

Different hypotheses of the organization of conceptual knowledge are more or less successful at accounting for different types of facts. Thus, it is important to consider the specific assumptions made by each hypothesis in the context of a broad range of empirical phenomena. The combination of neuropsychology and functional neuroimaging is beginning to provide promising grounds for raising theoretically motivated questions concerning the organization of conceptual knowledge in the human brain.

Catford, John C. (b. 1917)

J G Harris, Kirkland, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

J. C. Catford, Professor Emeritus of linguistics at the University of Michigan, USA, was born in Edinburgh, Scotland, in 1917. He studied at the Universities of Edinburgh, Paris, and London. He is, in the opinion of many, one of the greatest living linguists of the 20th and 21st centuries.

At age 14, inspired by Bernard Shaw's *Pygmalion,* he became deeply interested in phonetics, which he studied in Sweet's *Primer of phonetics,* and with encouragement from Daniel Jones (the leading British phonetician of the time). As a schoolboy he became competent in phonetic analysis and production, applying this skill to many English dialects and foreign languages. Having had an audition at the British Broadcasting Corporation, at 17 he began a long association with the BBC and parallel careers as a phonetician/linguist and a radio actor. At this time, his enthusiasm for phonetics broadened into a general interest in linguistics, on which he read widely in the works of Sweet, Jespersen, Sapir, Bloomfield, and others.

Specializing in French at Edinburgh University, he passed an academic year in France as an "assistant d'anglais" in a French lycée. During this time, he earned the Diplôme de Phonétique Générale of the Institut de Phonétique of the University of Paris, where he also attended lectures by Marcel Cohen and André Martinet. In 1939, he interrupted his studies to accept an invitation to teach at the British Council's Institute of English Studies in Athens for one year. The start of World War II prevented his return to Britain, so the one year became seven, during which he applied phonetics and linguistics in teaching English in Greece, Egypt, and Palestine, acquiring knowledge of Modern Greek, Arabic, and Hebrew. He also met speakers of Caucasian languages and was fascinated by their phonetics and grammar.

Returning to the UK in 1946, he studied general linguistics (with J. R. Firth) and Slavonic linguistics at London University, earning his living as a radio actor, specializing in 'exotic' dialects and foreign accents, i.e., doing applied phonetics, including the analysis of the sound systems of numerous languages, dialects, and even individuals, and then synthesizing approximately the same sounds in his own vocal tract.

In 1952, he returned to Edinburgh University to work full time on the Linguistic Survey of Scotland, where he designed a phonological, rather than phonetic, questionnaire for field work. In 1957, he created and became Director of the Edinburgh University School of Applied Linguistics – believed to be the first academic institution to specialize in the application of linguistic theory and data to practical problems such as language teaching and translation. In 1964, he was invited to the University of Michigan as a professor of linguistics and Director of the English Language Institute, subsequently Chairman of the Department of Linguistics, and Director of the Phonetics Laboratory. He taught phonetics and phonology, applied linguistics, translation theory, comparative-historical linguistics, and several other topics. He also developed his interest in Caucasian languages in two field trips to the USSR. In 1973, he conducted a seminar in Israel for Circassian

During this time, he earned the Diplôme de Phonétique Générale of the Institut de Phonétique of the University of Paris, where he also attended lectures by Marcel Cohen and André Martinet. In 1939, he interrupted his studies to accept an invitation to teach at the British Council's Institute of English Studies in Athens for one year. The start of World War II prevented his return to Britain, so the one year became seven, during which he applied phonetics and linguistics in teaching English in Greece, Egypt, and Palestine, acquiring knowledge of Modern Greek, Arabic, and Hebrew. He also met speakers of Caucasian languages and was fascinated by their phonetics and grammar.

Returning to the UK in 1946, he studied general linguistics (with J. R. Firth) and Slavonic linguistics at London University, earning his living as a radio actor, specializing in 'exotic' dialects and foreign accents, i.e., doing applied phonetics, including the analysis of the sound systems of numerous languages, dialects, and even individuals, and then synthesizing approximately the same sounds in his own vocal tract.

In 1952, he returned to Edinburgh University to work full time on the Linguistic Survey of Scotland, where he designed a phonological, rather than phonetic, questionnaire for field work. In 1957, he created and became Director of the Edinburgh University School of Applied Linguistics – believed to be the first academic institution to specialize in the application of linguistic theory and data to practical problems such as language teaching and translation. In 1964, he was invited to the University of Michigan as a professor of linguistics and Director of the English Language Institute, subsequently Chairman of the Department of Linguistics, and Director of the Phonetics Laboratory. He taught phonetics and phonology, applied linguistics, translation theory, comparative-historical linguistics, and several other topics. He also developed his interest in Caucasian languages in two field trips to the USSR. In 1973, he conducted a seminar in Israel for Circassian

teachers, on the Cyrillic orthography and the grammar of Adyghe, so that Circassian children in Israel could become literate in their own language.

After his retirement in 1986, he was Visiting Professor at the University of the Bosphorus, Istanbul, at the Hebrew University, Jerusalem, and at the University of California, Los Angeles. In 1988–1993, he was Executive Editor (translation) for the *Encyclopedia of language and linguistics* (Oxford, Pergamon Press, 1994), and wrote the encyclopedia articles 'Caucasian languages,' 'Articulatory phonetics,' and 'Translation, overview.'

His major contributions have been in phonetic taxonomy, aerodynamic phonetics, phonation types, Scots dialectology, Caucasian phonetics, applied linguistics, and translation theory. His *Fundamental problems in phonetics* (1977), *A practical introduction to phonetics* (1988), and articles on 'Phonation types' (1964) and 'The articulatory possibilities of man' (1968) are classics in the field.

Caucasian Languages

B G Hewitt, SOAS, Doncaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Around 38 languages are deemed to be indigenous to the Caucasus; often difficult demarcation between language and dialect explains the uncertainty. The ancestral homelands are currently divided between:

1. Russia's north Caucasian provinces (Circassian, Abaza, Ingush, Chechen, Avaro-Ando-Tsezic, Lako-Dargic, northern Lezgic);
2. *de facto* independent Abkhazia (Abkhaz, Mingrelian, Svan, Georgian, Laz);
3. Georgia (Georgian, Mingrelian, Svan, Laz, Bats, Chechen, Avar, Udi);
4. Azerbaijan (Lezgi, Budukh, Kryts', Khinalugh, Rutul, Ts'akhur, Avar, Udi) Turkey (Laz, Georgian).

Diaspora-communities of North (especially northwest) Caucasians can be found across former Ottoman territories, particularly Turkey, where the majority Circassian and Abkhazian populations reside and where the term 'Cherkess' often

teachers, on the Cyrillic orthography and the grammar of Adyghe, so that Circassian children in Israel could become literate in their own language.

After his retirement in 1986, he was Visiting Professor at the University of the Bosphorus, Istanbul, at the Hebrew University, Jerusalem, and at the University of California, Los Angeles. Caucasian Languages

B G Hewitt, SOAS, Doncaster, UK

© 2006 Elsevier Ltd. All rights reserved.

Around 38 languages are deemed to be indigenous to the Caucasus; often difficult demarcation between language and dialect explains the uncertainty. The ancestral homelands are currently divided between:

1. Russia's north Caucasian provinces (Circassian, Abaza, Ingush, Chechen, Avaro-Ando-Tsezic, Lako-Dargic, northern Lezgic);
2. *de facto* independent Abkhazia (Abkhaz, Mingrelian, Svan, Georgian, Laz);
3. Georgia (Georgian, Mingrelian, Svan, Laz, Bats, Chechen, Avar, Udi);
4. Azerbaijan (Lezgi, Budukh, Kryts', Khinalugh, Rutul, Ts'akhur, Avar, Udi) Turkey (Laz, Georgian).

Diaspora-communities of North (especially northwest) Caucasians can be found across former Ottoman territories, particularly Turkey, where the majority Circassian and Abkhazian populations reside and where the term 'Cherkess' often

indiscriminately applies to any North Caucasian. Circassians are found in Syria, Israel, and Jordan, home also to a significant Chechen population. Speaker numbers range from 500 (Hinukh) to 3–4 million (Georgian). Many of the languages are endangered.

Three families are usually recognized:

A. South Caucasian (Kartvelian)
   Georgian
   Svan
   Mingrelian (Megrelian)
   Laz (Ch'an)

[Scholars in Georgia regard Mingrelian and Laz as codialects of Zan]

B. North West Caucasian
   Abkhaz
   Abaza
   Ubykh (extinct from 1992)
   West Circassian (Adyghe)
   East Circassian (Kabardian)

C. Nakh-Daghestanian
   (*a*) *Nakh (North Central Caucasian)*
      Chechen
      Ingush
      Bats (Ts'ova Tush)
   (*b*) *Daghestanian (North East Caucasian)*

      1. Avaro-Ando-Tsezic(/Didoic):
         Avaric: **Avar**
         Andic: Andi, Botlikh, Godoberi, K'arat'a (Karata), Akhvakh, Bagvalal, T'indi (Tindi), Ch'amalal (Chamalal)
         Tsezic: Tsez (Dido), Khvarshi, Hinukh, Bezht'a (Bezhta) (K'ap'uch'a), Hunzib (these last two are sometimes regarded as codialects)

      2. Lako-Dargic:
         Lakic: **Lak**
         Dargic: **Dargwa** (Dargi(n)) – some treat K'ubachi, Chiragh, and Megeb as full languages

      3. Lezgic:
         Lezgi(an), **Tabasaran** (Tabassaran), Rutul (Mukhad), Ts'akhur (Tsakhur), Aghul, Udi, Archi, Budukh, Khinalugh, Kryts' (Kryts)

Some challenge the Lezgic status of Archi, Khinalugh, Budukh, and Kryts.' Mutual intelligibility basically exists between Laz and Mingrelian, Abkhaz, and Abaza, West and East Circassian. Only Georgian has an ancient tradition of writing, but during the Soviet period the languages in bold all enjoyed literary status. Publishing in Mingrelian, Laz, Ts'akhur, Aghul, Rutul, and Udi was tried in the 1930s but discontinued, though there have been some post-Soviet attempts to publish more widely (including Dido).

Phonetics and Phonology

All Caucasian languages have voiced vs. voiceless aspirate vs. voiceless ejective plosives, affricates, and occasionally fricatives, to which some add a *fortis* series (voiceless unaspirated or geminate). North West Caucasian is characterized by large consonantal inventories coupled with minimal vowel systems, consisting of at least the vertical opposition open /ɑ/ vs. closed /ə/. Ubykh possessed 80 phonemes (83 if the plain velar plosives attested only in loans are admitted), with every point of articulation between lips and larynx utilized and displaying the secondary features of palatalization, labialization, and pharyngalization – Daghestanian pharyngalization is normally assigned to vowels (Table 1).

Some recent analyses of Daghestanian languages have produced inventories rivaling those of the North West Caucasian, though no parallel minimality among the vowels is posited. One analysis of Archi assigns it 70 consonants (Table 2).

Noticeable here, is the presence of 10 laterals, though some specialists recognize no more than three or four.

Kartvelian occupies a mid-position with between 28 and 30 consonants (see Georgian). Georgian shares with Avar and Andi the simple five-vowel triangle (Table 3).

Schwa is added to this in the other Kartvelian languages, while the various Svan dialects have length and/or umlaut, Upper Bal having the richest system (Table 4).

Triangular or quadrilateral vowel systems are attested in Nakh-Daghestanian (Table 5).

All but /y, ɛ, œ/ possess long counterparts, and the nasalized vowels: /ĩ, ɛ̃, ɑ̃, ɔ̃, ũ, ũː, ã, ỹː/ have also been recognized. Table 6 shows the Hunzib basic vowels.

All these Hunzib vowels have long counterparts, and fluctuating nasalization on short vowels has been observed.

The simplest (near-)quadrilateral system is attested in Chiragh Dargwa, with four pairs distinguished by length (Table 7). Udi has been analyzed in Table 8, whilst Chechen presents the complicated system (Table 9).

Most, if not all, of these can be nasalized as a result of the weakening of a following /n/.

Stress is sometimes distinctive (Abkhaz-Abaza) but usually not. Tonal distinctions have been proposed for some of the Daghestanian languages (Andi, Akhvakh, Ch’amalal, Khvarshi, Hinukh, Bezht’a, Tabasaran, Ts’akhur, Ingush, and Budukh).

Morphology

North West Caucasian sememes are typically C(C)(V), and minimal case systems combine with highly polysynthetic verbs, which may contain up to four agreement prefixes, locational preverbs, orientational preverbs and/or suffixes, interrogative and conjunctional elements, and markers of tense-modality, (non-)finiteness, causation, potentiality, involuntariness, polarity, reflexivity, and reciprocality (see Abkhaz). Kartvelian balances a moderate total of cases with reasonably complex verbs, which may contain: agreement with two or three (rarely four) arguments via two sets of agreement affixes, directional/perfectivizing preverbs (the large total in Mingrelian-Laz suggests North West Caucasian influence), and markers of tense-aspect-modality, causation, potentiality, version (vocalic prefixes indicating certain relations between arguments), and voice –

Table 10 Avar locative case endings

Series	*Essive*	*Allative*	*Ablative*
1. 'on'	-d(.)ɑ	-d.ɛ	-d(.)ɑ.sːɑ
2. 'near'	-qː	-qː.ɛ	-qː.ɑ
3. 'under'	-k͡ɬːʼ	-k͡ɬːʼ.ɛ	-k͡ɬːʼ.ɑ
4. 'in (mass)'	-k͡ɬː	-k͡ɬː.ɛ	-k͡ɬː.ɑ
5. 'in (space)'	-D (= class-marker)	-D-ɛ	-sːɑ

Kartvelian is the only family to have a full active-passive diathetic opposition. Nakh-Daghestanian has complex nominal systems with both grammatical and sometimes large numbers of locative cases; Lezgi(an), Aghul, and Udi apart, nouns fall into one of between two and (depending on the analysis) five or eight (largely covert) classes. Verbs are correspondingly simple: agreement is totally absent from Lezgi(an) and Aghul; elsewhere, verbs with an agreement slot typically allow only class agreement (Andic), though some languages (Bats, Lak-Dargwa, Tabasaran, Akhvakh, Archi, Hunzib, and Avar dialects) have added perhaps rudimentary person agreement, whilst Udi has person agreement only. Some languages have a small selection of preverbs. Some distinguish perfective from imperfective roots. Some North Caucasian verbs can be construed transitively or intransitively (?passively), depending on the clausal structure. Antipassives are also attested.

Avar illustrates a typical system of locative-cases (Table 10).

Ergativity and some other oblique case function are often merged in a single morph.

Deictic systems range from two-term (Mingrelian, Ubykh, Kryts'), through three-term (Georgian, Abkhaz, Circassian), to five-term in a swathe of Daghestanian, and even six-term (Lezgi(an), Godoberi).

Counting systems are predominantly vigesimal, at least up to '99' (though Bats is vigesimal throughout), but some systems are decimal.

Syntax

Word orders are: Kartvelian and Nakh-Daghestanian AN, GN, N-Postposition, SOV, though Old Georgian was rather NA and NG; North West Caucasian GN, predominantly NA, N-Postposition, SOV. Some degree of ergativity characterizes all the languages, but in Mingrelian, where the system was originally as illustrated for Georgian (*q.v.*), the ergative case marker was extended vertically to replace the original nominative for intransitive (including indirect) verbs in Series II (aorist indicative and subjunctive), where it functions as a Series II nominative allomorph, the original nominative effectively becoming an accusative just for Series II. Laz has extended the case marker horizontally across its three series for all transitive subjects. Active–inactive alignment plays a role in some languages (Bats).

A nominative/absolutive argument is the obligatory minimum in a clause, and where verbs have class agreement, this is the determiner for the class marker (which in some languages also appears on adverbs and as part of a locative case exponent); the determiner for person agreement in languages with class agreement might be this same or a different argument (e.g., the logical subject), depending on a variety of factors.

Verbs such as *want*, *have*, *hear* are construed indirectly with the logical subject in an oblique case, but, if Kartvelian and North West Caucasian employ just the dative/general oblique case for this argument, greater distinctions can apply in Nakh-Daghestanian: Avar employs its dative case with verbs of emotion (*love*), a locative (Series I essive) with verbs of perception (*see*), and the genitive for the possessor in conjunction with the copula.

Only Kartvelian has the category of subordinating conjunctions, naturally associated with full clauses containing indicative or subjunctive finite verbs. Such structures are rare in North Caucasian, where one finds a variety of nonfinite (nominalized) verb forms fulfilling the subordinate role.

Examples:

'It became impossible for the north wind not to admit how/that the sun is stronger than it'
(Temirgoi West Circassian)

Kinship

Kartvelian is unrelated to any known language or language family, but the debate continues concerning the relationship between the northern families. Linkage to Hattic is postulated for northwestern Caucasian and to Hurrian for Nakh-Daghestanian. Udi has recently been conclusively demonstrated to descend from Caucasian Albanian.

Causatives: Semantics

J J Song, University of Otago, Dunedin, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Defining Causative Constructions

The causative construction is a linguistic expression that denotes a complex situation consisting of two events: (1) the causing event in which the causer does something, and (2) the caused event in which the causee carries out an action or undergoes a change of condition or state as a result of the causer's action. The following example is such a linguistic expression.

(1) The teacher made Matthew paint the house

In (1), the causer (*the teacher*) did something, and as a result of that action the causee (*Matthew*) in turn carried out the action of painting the house.

The causative construction has two main characteristics. First, the causer noun phrase and the expression of cause must be foregrounded, with the causee noun phrase and the expression of effect backgrounded. The foregrounding of the causer noun phrase and the expression of cause is achieved by putting these two expressions in grammatically more prominent positions in the sentence than the causee noun phrase and the expression of effect. Second, the expression of the causer's action must be without specific meaning; all that is encoded by that expression is the pure notion of cause. For instance, the sentence in (2), although denoting a causative situation similar to (1), is **not** regarded as an example of the causative construction but rather as an example of what may be referred to broadly as the causal construction.

(2) Matthew painted the house because the teacher instructed him to do so

There are two clear differences between (1) and (2). First, in (1) the causer noun phrase, *the teacher*, and the expression of cause, *made*, are the subject and the main predicate of the sentence, respectively (i.e., they are foregrounded). The causee noun phrase and the predicate of effect, on the other hand, appear as a nonsubject noun phrase and a subordinate predicate, respectively (i.e., they are backgrounded). This situation is reversed in (2); the causee noun phrase and the expression of effect appear as the subject and the predicate of the main clause, respectively, with both the causer noun phrase and the expression of cause located in the subordinate clause. Second, in (1) the expression of the causer's action, *made,* lacks specific lexical content. In (2), on the other hand, the expression of the causer's action, *instructed* has specific lexical content.

Types of Causative Constructions

The most widely known classification of causatives is based on the formal fusion between the predicate of cause and that of effect. In this classification, three different types of causative are recognized: (1) lexical, (2) morphological, and (3) syntactic.

The lexical causative type involves suppletion (no formal similarity between the noncausative verb and its causative counterpart). In this type, the formal fusion of the expression of cause and of effect is maximal, with the effect that the causative verb cannot be analyzed into two morphemes. Examples of

Causal Theories of Reference and Meaning

A Sullivan, Memorial University of Newfoundland, St. John's NL, Canada

© 2006 Elsevier Ltd. All rights reserved.

Reference, Meaning, and Causal Theories

The theory of reference and the theory of meaning are two closely related, fundamental strains within the study of mind and language. The aim of a theory of meaning is to explain what it is that competent speakers of a given language know, or are able to do, in virtue of which they are able to use the language to communicate. The aim of the theory of reference is to explain what it is in virtue of which words refer to what they do, how it is that utterances can hook onto and express information about particular things.

The exact relation between meaning and reference is a controversial matter (in large part because of the wide variety of theoretical approaches to meaning). According to some views, the meaning of an expression is precisely its referent, and so theories of meaning and of reference are just slightly different roads in to what is essentially the same task. Opponents of this notion point to co-referential expressions that differ in meaning (such as 'Portugal' and 'the country immediately west of Spain'), or to meaningful expressions that do not seem to refer to anything ('of', or 'for the sake of'), to show that meaning is distinct from reference. Or again, many theorists hold that proper names refer but cannot really be said to have a meaning, or that complete sentences have a determinate meaning but do not refer to anything.

In any case, the causal theory of reference (i.e., words refer to what they do by virtue of a certain sort of causal relation between word and referent) and the causal theory of meaning (i.e., words mean what they do by virtue of a certain sort of causal relation between word and meaning) are, historically and conceptually, distinct views. To help avoid confusion, I will distinguish the relevant approach to reference by calling it 'the causal-*historical* theory.' ('Historical' is an appropriate distinguishing mark because the history of how a word is transmitted from its original inception to the current speaker ismuch more important on the causal approach to reference, as compared with the causal approach to meaning.)

The Causal-Historical Theory of Reference

The causal-historical theory of reference was developed in the 1960s and 1970s. It is explicitly developed only for proper names (cf. Donnellan, 1970; Kripke, 1972) and natural kind terms (cf. Kripke, 1972; Putnam, 1975). However, Kaplan (1977) raises some related points about indexical expressions, and there have been attempts to fashion a fully general approach to reference along these lines (for discussion, see Stalnaker, 1997; Devitt and Sterenly, 1999). The theory has replaced the descriptivist approach to reference, different versions of which were defended by Frege and Russell, as the orthodox approach to reference. (*see* **Proper Names: Philosophical Aspects** for discussion.)

According to the causal-historical theorists, descriptivists are wrong to demand that, in order to significantly use a term, speakers need to have a uniquely identifying description of its referent. Rather, once a convention is in place, linking a term to its referent, a deferential intention to comply with this practice – i.e., to use 'X' to refer to what others have used 'X' to refer to – is all that is required in order to use the term to refer. The view has it that certain expressions refer to certain things in virtue of a causal-historical relation between word and object, initially fixed during a dubbing or baptism and propagated from there to subsequent speakers, who implicitly defer to that initial dubbing in using the expression to refer.

The notion of a causal-historical chain as that which is criterial in determining reference is developed more or less independently by Donnellan and Kripke. Donnellan (1970: 277) concludes an argument against descriptivism with the claim that "... in some way the referent must be historically, or, we might say, causally connected to the speech act." Donnellan (1974: 17) articulates the point at a bit more length: "Suppose someone says 'Socrates was snub-nosed', and we ask to whom he is referring....[T]his calls for a historical explanation; we search not for an individual who might best fit the speaker's descriptions ... but rather for an individual historically *related* to his use of the name." Kripke (1972: 94–95) uses similar terms to describe his approach: "...It's in virtue of our connection with other speakers in the community, going back to the referent himself, that we refer to a certain man ... In general, our reference depends not just on what we think ourselves, but on other people in the community, the history of how the name reached one, and things like that. It is by following such a history that one gets to the reference." And again Kripke (1972: 106): "... reference actually seems to be determined by the fact that the speaker is a member of a community of speakers who use the name.

The name has been passed to him by tradition from link to link."

The causal-historical theory is an externalist approach to reference, in that reference depends largely on factors external to the speaker's head – factors pertaining to the speaker's linguistic community and to the environment in which the expression in question evolved. (Descriptivists tend to be internalists, insofar as they hold that reference is fully determined by the speaker's beliefs and discriminative abilities.) On the causal-historical view, the criteria for the correct application of a word are not, in general, introspectively accessible to competent speakers; one can competently use 'gold' or 'Aristotle' without knowing anything that would distinguish Aristotle from Plato, or gold from fool's gold. Mistaken or ignorant speakers can still single out specific referents via these complex, communal, causal-historical mechanisms. (*see* **Externalism about Content** for more on this.)

Contra the descriptivists, the causal-historical theorists argue that the meaning of a proper name is not some kind of descriptive sense (*see* **Direct Reference; Proper Names: Philosophical Aspects; Reference: Philosophical Theories** for discussion). From here, the conclusion that the semantic contribution of a name is just its referent looks compelling. This is why the theory has led to a resurgence of interest in the Millian view of proper names (i.e., the meaning of a name it just its referent) and in the Russellian approach to singular propositions (i.e., the proposition expressed by a sentence containing a name – say, 'Kaplan is in California' – is individuated solely in terms of the individual and property that it is about, as opposed to being individuated in terms of more finely-grained concepts or meanings). Many think that the causal-historical chain of transmission story about how a word refers to something in particular nicely complements, and fleshes out, these doctrines of Mill and Russell.

The causal-historical theory does not aim to aim to give a reductive analysis of reference. For example, Kripke (1972: 96) says: "When the name is 'passed from link to link,' the receiver of the name must, I think, intend to use it with the same reference as the man from whom he heard it . . . [T]he preceding account hardly *eliminates* the notion of reference; on the contrary, it takes the notion of intending to use the same reference as a given." (Cf. Kaplan's [1990] discussion of the point that the intention to preserve reference is not itself a causal notion.) Thus, those who seek to naturalize reference, by reducing the relation of reference to something more scientifically respectable, must either significantly alter the causal-historical view, or look elsewhere.

The Causal Theory of Meaning

In contrast, the causal theory of meaning (also called the 'information-theoretic' approach to meaning) is explicitly in the business of explaining semantic phenomena in non-semantic terms. The general aim here is a naturalistic account of the phenomenon of meaning, and the thought is that the notion of causation is the most promising place from which to start. Dretske (1981) is a seminal proponent of this approach, and Fodor (1987, 1990) develops related accounts. Stampe (1977), another influential proponent, gives the following programmatic sketch: "We have causal theories . . . of knowledge and memory, of belief, of evidence, of proper and common names, and of reference. If . . . these phenomena should turn out to have causal analyses, it will be no mere coincidence. Only their having something in common would make it so . . . [The root of this convergence] is that *representation* is essentially a causal phenomenon" (1977: 81).

The general idea behind the causal theory of meaning is that linguistic meaning is a species of causal co-variance. Roughly, the goal is to show that 'means' means (more or less) the same thing in (1) and (2), that both cases are, at root, cases of reliable correlation:

1. Smoke means fire.
2. 'Fire' means fire.

For a word to mean something in particular is for the word to reliably indicate that thing. Alternatively, a word 'W' means M if M tends to cause or bring about tokens of 'W.' (The account is intended to apply not only to tokens of 'W' that are actually uttered, but also, and more fundamentally, to occurrences of the word in thought.)

If a satisfactory account of meaning were forthcoming down this avenue, this would be a monumental leap forward for the human and cognitive sciences. As yet, there is nothing remotely resembling a satisfactory scientific treatment of meaning; given the fundamental and pervasive roles that meaningful thoughts and utterances play in our lives, that is a rather large gap in our scientific understanding of human beings.

(Note that Grice [1957] criticizes a view that he calls 'the causal theory of meaning' – the core of which is the idea that the meaning of an expression 'E' is (roughly) the content of the attitude that is prone to cause a speaker to utter 'E,' and that hearing 'E' is prone to cause in listeners. This view has not played a major role in the philosophy of language; but nonetheless some of Grice's arguments against it are echoed in the criticisms, described in the next section, of the above information-theoretic causal theory.)

Problems and Prospects

There are many problems with the causal-historical theory of reference (which are discussed at more length in **Reference: Philosophical Theories**). Evans (1973) and Searle (1983) develop counterexamples to the theory, cases where it seems to be committed to unwelcome consequences. Furthermore, many of the semantic views with which the theory has been allied (such as those of Mill and Russell mentioned earlier in the second section of this article) are controversial (*see* **Direct Reference; Proper Names: Philosophical Aspects** for discussion). More generally, the causal-historical view is just a sketchy picture – it does not offer anything like specific necessary or sufficient causal-historical conditions for identifying the referent of an utterance or inscription. Any utterance stands in an awful lot of causal relations to an indefinite range of things; to single out precisely which subset of these ubiquitous causal relations are semantically relevant – let alone precisely which of them are relevant to determining the referent of a particular use of a particular expression – is a daunting task that is as yet barely begun.

The situation is worse for the (more reductionist, and so more ambitious) causal theory of meaning. It not only falls prey to the problems that befalls the causal-historical approach to reference but also gives rise to some distinctive problems of its own. Basically, for almost any word-meaning pair 'W'-M, it is not difficult to come up with conditions in which things distinct from M tend to cause 'W's, and conditions in which M does not tend to cause 'W's. For instance, in various sorts of suboptimal conditions, cows might tend to cause tokens of 'horse,' but nonetheless – regardless of how dark it is (or how far away they are, what they are disguised as, etc.) – these cows are distinct from the meaning of 'horse.' In the other direction, if a horse was to 'baa' like a sheep, or was painted with zebra-stripes, or what have you, these misleading factors would affect its tendency to cause 'horse'-tokens, but would not have the slightest effect on the fact that the term 'horse' correctly applies to it. In short, causation is a much more undiscriminating relation than meaning; and this is the source of all manner of problems for the project of using causation to build an account of meaning.

There are many refinements of the basic causal-theoretic view, intended to skirt these elementary problems and their many variants. However, the consensus seems to be that this type of causal theory can only succeed in delivering an account of meaning that accommodates our intuitions about the normativity and determinacy of meaning (i.e., respectively, it is possible to misapply a term, and the terms 'A' and 'B' can differ in meaning even if all As are Bs) if it smuggles in semantic notions, and thus helps itself to meaning, as opposed to offering an account of meaning (for discussion, see Loewer, 1997).

To sum up: the causal theory of reference is the view that a word refers to that to which it stands in the right sort of causal-historical relation. Since the 1970s, it has become the orthodox approach to reference. However, many problems remain to be worked out, for this general picture to yield a satisfactory, comprehensive account of reference. The causal theory of meaning is the view that the meaning of a word is that which reliably causes tokens of the word to be thought or uttered. Many take this to be the most promising avenue for a naturalistic account of meaning. However, there are reasons to think that the approach is too crude to yield an adequate account of linguistic meaning. At best, there are counterexamples that have yet to be satisfactorily addressed.

Catalan

M W Wheeler, University of Sussex, Brighton, UK

© 2006 Elsevier Ltd. All rights reserved.

Geography and Demography

The territories where Catalan is natively spoken cover 68 730 km^2, of which 93% lies within Spain (see **Figure 1**). They are:

1. The Principality of Andorra
2. In France: North Catalonia – almost all of the département of Pyrénées-Orientales
3. In Spain: Catalonia, except for the Gascon-speaking Vall d'Aran; the eastern fringe of Aragon; most of Valencia (the Comunitat Valenciana), excepting some regions in the west and south that have been Aragonese/Spanish-speaking since at least the 18th century; El Carxe, a small area of the province of Murcia, settled in the 19th century; and the Balearic Islands
4. In Italy: the port of Alghero (Catalan *L'Alguer*) in Sardinia

Table 1 shows the population of these territories (those over 2 years of age in Spain) and the percentages of the inhabitants who can understand, speak, and write Catalan. Information is derived from the 2001 census in Spain together with surveys and other estimates; the latter are the only sources of language data in France and Italy. The total number of speakers of Catalan is a little under 7.5 million. Partly as a result of the incorporation of Catalan locally into the education system, there are within Spain a significant number of second-language speakers who are included in this total. Virtually all speakers of Catalan are bilingual, using also the major language of the state they live in. (Andorrans are bilingual in Spanish or French, or are trilingual.)

Genetic Relationship and Typological Features

Catalan is a member of the Romance family and a fairly prototypical one, as befits its geographically central position in the European Romance area. Some particularly noteworthy characteristics are pointed out here (for more details see Wheeler, 1988). In historical phonology, note the palatalization of initial /l-/ and loss of stem-final /n/ that became word final, for example, LEONEM > *lleó* [ʎə'o] 'lion.' Original intervocalic -C′-, -TJ-, -D- became /w/ in word-final position and were lost elsewhere, for examples, PLACET > *plau* ['plaw] 'please.3.SING,' PLACEMUS > *plaem* [plə'ɛm] 'please. 1.PL.' As the previous examples also illustrate, posttonic nonlow vowels were lost, so that a dominant pattern of phonological words is of consonant-final oxytones. The full range of common Romance verbal inflection is retained, including inflected future (*sentirà* 'hear.3.SING.FUT'), widely used subjunctives, and a contrast between present perfect (*ha sentit* 'has heard') and past perfective (*sentí* 'heard.3.SING. PERF'). In addition to the inherited past perfective form, now largely literary, Catalan developed a periphrastic past perfective using an auxiliary that was originally the present of 'go' (*va sentir* 'AUX. PERF.3.SING hear.INF'). In some varieties of Catalan, this construction has developed a subjunctive (*vagi sentir* 'AUX.PERF.SUBJ.3.SING hear.INF'), introducing, uniquely in Romance, a perfective/imperfective aspect distinction in the subjunctive. Considerable use is made of pronominal and adverbial clitics that attach to verb forms in direct and indirect object functions or partitive or adverbial functions, quite often in clusters of two or three, as in (1).

(1) us n'hi envi-en
2.PL.OBJ PART.LOC *send*-3.PL
"they send some to you (PL) there"

Most of the pronominal/adverbial clitics have several contextually conditioned forms; thus, the partitive clitic shows variants *en* ∼ *n'* ∼ *-ne*. Clitic climbing is commonly found with a pronominal complement of a verb that is itself the complement of a (semantic) modal, as in (2). This example also shows the (optional) gender agreement of a perfect participle with a preceding direct object clitic.

(2) no l'he sab-ud-a agafa-r
not DO.3.SING.F. *know*- *catch*-INF
have.1.SING PART-F
"I haven't been able to catch it (FEM)"

Causatives: Semantics

J J Song, University of Otago, Dunedin, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Defining Causative Constructions

The causative construction is a linguistic expression that denotes a complex situation consisting of two events: (1) the causing event in which the causer does something, and (2) the caused event in which the causee carries out an action or undergoes a change of condition or state as a result of the causer's action. The following example is such a linguistic expression.

(1) The teacher made Matthew paint the house

In (1), the causer (*the teacher*) did something, and as a result of that action the causee (*Matthew*) in turn carried out the action of painting the house.

The causative construction has two main characteristics. First, the causer noun phrase and the expression of cause must be foregrounded, with the causee noun phrase and the expression of effect backgrounded. The foregrounding of the causer noun phrase and the expression of cause is achieved by putting these two expressions in grammatically more prominent positions in the sentence than the causee noun phrase and the expression of effect. Second, the expression of the causer's action must be without specific meaning; all that is encoded by that expression is the pure notion of cause. For instance, the sentence in (2), although denoting a causative situation similar to (1), is **not** regarded as an example of the causative construction but rather as an example of what may be referred to broadly as the causal construction.

(2) Matthew painted the house because the teacher instructed him to do so

There are two clear differences between (1) and (2). First, in (1) the causer noun phrase, *the teacher*, and the expression of cause, *made*, are the subject and the main predicate of the sentence, respectively (i.e., they are foregrounded). The causee noun phrase and the predicate of effect, on the other hand, appear as a nonsubject noun phrase and a subordinate predicate, respectively (i.e., they are backgrounded). This situation is reversed in (2); the causee noun phrase and the expression of effect appear as the subject and the predicate of the main clause, respectively, with both the causer noun phrase and the expression of cause located in the subordinate clause. Second, in (1) the expression of the causer's action, *made,* lacks specific lexical content. In (2), on the other hand, the expression of the causer's action, *instructed* has specific lexical content.

Types of Causative Constructions

The most widely known classification of causatives is based on the formal fusion between the predicate of cause and that of effect. In this classification, three different types of causative are recognized: (1) lexical, (2) morphological, and (3) syntactic.

The lexical causative type involves suppletion (no formal similarity between the noncausative verb and its causative counterpart). In this type, the formal fusion of the expression of cause and of effect is maximal, with the effect that the causative verb cannot be analyzed into two morphemes. Examples of

this type include, English *die* vs. *kill* and German *sterben* 'to die' vs. *töten* 'to kill.'

In the morphological type, the expression of cause is in the form of a derivational affix, with the expression of effect realized by a basic verb to which that affix is attached. In Japanese, for example, the suffix *-(s)ase* can apply to basic verbs to derive causative verbs, for example, *ik-* '[X] to go' vs. *ik-ase-* 'to cause [X] to go.' The causative morpheme can be in the form of not only suffixes but also prefixes, infixes, and circumfixes.

In the syntactic type, the expression of cause and of effect are separate verbs, and they occur in different clauses. This type has already been exemplified by (1). Swahili provides another good example (Vitale, 1981: 153).

(3) Ahmed a-li-m-fanya mbwa a-l-e
Ahmed he-PAST-him-make dog he-eat-SUBJ
samaki mkubwa
fish large
'Ahmed made the dog eat a large fish'

The three causative types must be understood to serve only as reference points. There are languages that fall somewhere between any two of the ideal types. For instance, Japanese lexical causative verbs lie between the lexical type and the morphological type because they exhibit degrees of physical resemblance – from almost identical to totally different – to their corresponding noncausative verbs, for example, *tome-* 'to cause [X] to stop' vs. *tomar-* '[X] to stop,' *oros-* 'to bring down' vs. *ori-* 'to come down,' *age-* 'to raise' vs. *agar-* 'to rise,' and *koros-* 'to kill' vs. *sin-* 'to die.'

The Semantics of Causatives: Two Major Types of Causation

As previously described, the causative construction is a linguistic expression that denotes a situation consisting of two events: (1) the causing event in which the causer does something, and (2) the caused event in which the causee carries out an action or undergoes a change of condition or state as a result of the causer's action. There are two mixed but distinct levels of description contained in this definition: the level of events and the level of participants. The first level is where the relationship between the causing event and the caused event is captured. The second level concerns the interaction between the causer and the causee. Most descriptions of the semantics of causatives revolve around these two levels of description.

Two major causation types – the distinction between direct and indirect causation, and the distinction between manipulative and directive causation – are discussed in this article because they are most highly relevant to the three causative types (lexical, morphological, and syntactic) previously described. The first semantic type of causation is based on the level of events; and the second is based on the level of participants.

The distinction between direct and indirect causation hinges on the temporal distance between the causing event and the caused event. If the caused event is temporally adjacent to the causing event, without any other event intervening between them, the overall causative situation may be regarded as direct. For example, if X makes Y fall into the river by pushing Y, the causing event of *X pushing Y* immediately precedes the caused event of *Y's falling into the river.* There is no intervening or intermediary event that plays a role in the realization of the caused event; in direct causation, the caused event is immediately temporally adjacent to the causing event. As a matter of fact, the temporal distance between cause and effect in direct causation may be so close that it sometimes becomes difficult perceptually, if not conceptually, to divide the whole causative situation into the causing event and the caused event (e.g., *the cat jumped as John slammed the door*). Thus, direct causation represents a causative situation in which the causing event and the caused event abut temporally on one another, the former immediately preceding the latter.

Indirect causation, on the other hand, involves a situation in which the caused event may not immediately follow the causing event in temporal terms. There will be at least one event intervening between the causing and caused events. In order for this to be the case, however, the temporal distance between the two events must be great enough for the whole causative situation to be divided clearly into the causing event and the caused event. For example, X fiddles with Y's car, and days later Y is injured in a car accident due to the failure of the car. In this situation, the causing event is *X's fiddling with Y's car* and the caused event is *Y's getting injured in the accident*. But these events are separated temporally from one another by the intermediary event (the failure of the car). The intervening event plays an important role in bringing about the caused event. Note that, although this causative situation is indirect, the caused event is connected temporally with the causing event in an inevitable flow or chain of events: Y's accident caused by the failure of the car and the failure of the car in turn caused by X's fiddling with it (e.g., Croft, 1991). There can potentially be more than one event intervening between the causing event and the caused event in indirect causation.

The other level of description involves the major participants of the causative situation, namely the causer and the causee. Depending on the nature and

extent of the causer's relationship with the causee in the realization of the caused event, the causative situation may be either manipulative or directive. If the causer acts physically on the causee, then the causative situation is regarded as manipulative. The causer manipulates the causee in bringing about the caused event. The situation used previously to exemplify direct causation is also manipulative because the causer physically pushes the causee into the river. In other words, this particular causative situation represents direct and manipulative causation. The causer may rely on an intermediary physical process or means in effecting the caused event. For example, if X causes Y to fall by pushing a shopping trolley straight into Y, the causer effects the caused event through some physical means, as in the case of direct manipulative causation already discussed. But this intermediary physical process also represents an independent event intervening between the causing event and the caused event – in fact, this intermediary event itself constitutes a causative situation consisting of a causing event (X exerting physical force directly on the shopping trolley) and a caused event (the shopping trolley rolling straight into Y). The causative situation in question may thus be regarded as indirect and manipulative causation.

The causer may also draw on a nonphysical (e.g., verbal or social) means in causing the causee to carry out the required action or to undergo the required change of condition or state. For example, if medical doctor X causes patient Y to lie down for a medical examination by giving Y an instruction or direction to do so, the causative situation is directive causation. This particular situation is also direct in that there is no other event intervening between the causing event and the caused event – Y's lying down is immediately temporally adjacent to X's uttering the instruction. Again, directive causation may also be indirect rather than direct. For example, if X causes Y to type a letter by giving Z an instruction to cause Y to do the typing, then we are dealing with indirect directive causation (e.g., *I had the letter typed by Tim by asking Mary to tell him to do so*). The caused event is separated from the causing event by the intervening event of Z asking Y to comply with X's original instruction.

Causative Continuum and Causation Types

There is a strong correlation between the causative and the causation types. The three causative types – lexical, morphological, and syntactic – can be interpreted as forming a continuum of formal fusion or physical propinquity between the expressions of cause and of effect, as schematized in Figure 1.

Figure 1 Continuum of formal fusion.

There is a strong tendency for manipulative or direct causation to be mapped onto the causative types on the left of the continuum in preference to those on the right of the continuum. Directive or indirect causation, on the other hand, is far more likely to be expressed by the causative types on the right of the continuum than by those on the left of the continuum. This is often cited in the literature as an excellent example in support of iconic motivations in language. Iconic motivation (or iconicity) is the principle that the structure of language should, as closely as possible, reflect the structure of what is expressed by language (e.g., Haiman, 1985). Recently, the correlation between the causative and causation types has been reinterpreted as that between the degree of difficulty in bringing about the caused event and the degree of transparency in expressing the notion of causation (Shibatani, 2002). For example, directive (as opposed to manipulative) causation involves a nonphysical (verbal or social) means of causing the causee to carry out the required action or to undergo the required change of condition or state. Directive causation entails a higher degree of difficulty in bringing about the caused event than manipulative causation. For one thing, in directive causation the causer relies on the causee's cooperation; the (prospective) causee can refuse to comply with the (prospective) causer's wish or demand. This higher degree of difficulty in bringing about the caused event is then claimed to be reflected by the tendency for directive causation to be expressed by the causative types to the right, rather than the left, on the continuum. The notion of causation is much more transparently encoded in the syntactic causative (i.e., a separate lexical verb of cause) than in the lexical causative, where the notion of causation is not expressed by a separate morpheme, let alone by a separate verb.

Moreover, there is a large amount of cross-linguistic evidence in support of the case marking of the causee being determined by semantic factors relating to the agency, control, affectedness, or even topicality of the main participants of the causative situation (e.g., Cole, 1983). In Bolivian Quechua, for example, the causee noun phrase is marked by the accusative case if the causee is directly under the causer's authority and has no control over his or

her action. If, however, the causee has control over his or her action but complies voluntarily with the causer's wish, the causee noun phrase appears in the instrumental case. Some linguists have made an attempt to reinterpret such variable case marking to reflect the conceptual integration of the causee in the causative event as a whole (Kemmer and Verhagen, 1994). This fits in well with the view that the simple noncausative clause pattern serves as a structural model for morphological causatives (Song, 1996). The causative of intransitive verbs is based on the transitive clause pattern, and the causative of transitive verbs is based on either the ditransitive clause pattern or the transitive clause pattern with an adjunct.

Caxton, William (ca. 1415–1491)

W Hüllen, Dusseldorf, Germany

© 2006 Elsevier Ltd. All rights reserved.

William Caxton (Cauxton, Causton) was born in Tenterden, Kent, some time between 1411 and 1422, and died in Westminster in 1491. After an apprenticeship as a mercer in London, he left for Bruges in 1446, where he went into business on his own. He stayed there for 30 years acting as a governor of the Merchant Adventurers between 1462 and 1465, a post that gave him considerable influence in the supervision of trade between the Low Countries and England. After 1468, he was able to establish close contact with the Duke of Burgundy, who had married Edward IV's sister. But after 1470 he relinquished all his commercial and political offices for good.

Caxton's interests in printing and in translating went hand in hand because, in addition to other titles, he was eager to print his own works. Between 1471 and 1474, he informed himself in Cologne about printing techniques but published his translation of *The recuyell of the histories of Troy*, which he had begun as a preventive against idleness (Dictionary of National Biography), in Bruges in the latter year at a press owned by Colard Mansion. It was the first book printed with movable letters in the English language.

He then moved to London, where he stayed for the rest of his life. In 1477, he issued *The dictes and sayings of the philosophers* from his own press. It was the first English book printed in England.

her action. If, however, the causee has control over his or her action but complies voluntarily with the causer's wish, the causee noun phrase appears in the instrumental case. Some linguists have made an attempt to reinterpret such variable case marking to reflect the conceptual integration of the causee in the causative event as a whole (Kemmer and Verhagen, 1994). This fits in well with the view that the simple noncausative clause pattern serves as a structural model for morphological causatives (Song, 1996). The causative of intransitive verbs is based on the transitive clause pattern, and the causative of transitive verbs is based on either the ditransitive clause pattern or the transitive clause pattern with an adjunct.

He stayed there for 30 years acting as a governor of the Merchant Adventurers between 1462 and 1465, a post that gave him considerable influence in the supervision of trade between the Low Countries and England. After 1468, he was able to establish close contact with the Duke of Burgundy, who had married Edward IV's sister. But after 1470 he relinquished all his commercial and political offices for good.

Caxton's interests in printing and in translating went hand in hand because, in addition to other titles, he was eager to print his own works. Between 1471 and 1474, he informed himself in Cologne about printing techniques but published his translation of *The recuyell of the histories of Troy*, which he had begun as a preventive against idleness (Dictionary of National Biography), in Bruges in the latter year at a press owned by Colard Mansion. It was the first book printed with movable letters in the English language.

He then moved to London, where he stayed for the rest of his life. In 1477, he issued *The dictes and sayings of the philosophers* from his own press. It was the first English book printed in England.

Between then and his death he produced the incredible output of about 70 books, almost all of them in folio, 21 being his own translations. He edited Chaucer (providing the *editio princeps* of the *Canterbury tales*), Lydgate, Gower, *The chronicle of Brut*, and also pamphlets, *horae*, and speeches. He translated French versions of Latin classical literature and of the philosophers and issued similar translations by others. For experts in printing techniques, his works are recognizable by the founts, which, however, he changed six times, and by such conspicuous signs as the absence of title pages, of ordinary commas and full stops, and of catchwords at the foot of each page. He was the first printer to include woodcuts.

Although he ushered in the new era of printed culture, his influence on the history of English is somewhat indirect. He did not contribute to the standardization of spelling, which was achieved only a century later. His own personal style, as visible in the prologues and epilogues of editions, was quite traditional, with Germanic lexis and syntax, including alliterations. In his translations, however, he conformed with the style of his mostly French authors, which led to a massive acceptance of French words, the abundant use of synonyms, elaborate forms of address, rhetorical figures, etc. Caxton's connection with the court of Burgundy may have been the personal background for this. In doing so and by the sheer mass of books he produced, he supported and reinforced the development of a 'curial' (or 'clergial,' 'aureate') style that was typical of the development of Middle English and brought the language into its own. His edition of a book of French and English conversations, which he probably translated himself, shows a new way of teaching foreign languages in schools, in which the old habit of printing topically ordered vocabulary is embedded in a method of presenting natural dialogues and role play.

Cayman Islands: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

The official language of the Cayman Islands is English, with 36 000 speakers. Literacy is 98%. There also exist sizable minority languages of Haitian Creole French, French, and Spanish. Cayman Islands English, although structurally similar to a creole, seems to have borrowed some creole features of Jamaican without having undergone creolization. Unlike many of the other islands in the Caribbean, the Cayman Islands were not directly subject to the pressures exerted by slavery and the plantation system. Instead, early settlers were turtle fishers and wreck salvagers. Population growth forced some emigration to islands off the coast of Central America, the Bay Islands and Corn Island. Strong trading ties also exist with Belize and Jamaica. These population movements and commercial links probably contributed towards language contact and borrowing; however, the lack of a large non-English population seems to have inhibited the development of a true creole.

Cebuano

J U Wolff, Cornell University, Ithaca, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Cebuano is spoken in the central and southern Philippines. It is a member of the Austronesian family of languages, the group of languages spoken throughout most of Indonesia, northward into the Philippines and Taiwan and eastward through much of Papua New Guinea and over the Pacific as far Hawaii and Easter Island. The languages of the Philippines, with the exceptions of the Spanish Creoles, Chabacano and Chavacano, are closely related and typologically similar to one another. In particular, Cebuano is subgrouped with Tagalog and is similar to Tagalog in much the same way as Italian and Spanish are similar to each other (*see* **Tagalog**). Cebuano is called *Sinugbaʔanun* or *Sinibuwanú* natively, and is sometimes referred to as 'Sugbuanon' in the literature about the language. Cebuano is also commonly called 'Visayan' (*Binisayaʔ* natively), after the name of the region of the central Philippines. However, there are in fact more than 30 languages spoken in this area, all of which are referred to as 'Visayan,' such that many publications referring to 'Visayan' have to do with languages other than Cebuano.

Cebuano is spoken by somewhere around a fifth of the population of the Philippines. It is thus second only to Tagalog in number of speakers. Throughout the 20th century Cebuano was widely used as a lingua franca in Mindanao and was almost universally known as a second language by those in Mindanao who were not native speakers of Cebuano. At the present time Tagalog is gaining as the lingua franca at the expense of Cebuano, and in Mindanao, as throughout the Cebuano speech area, native speakers of Cebuano are more and more learning Tagalog as a second language. Cebuano is considered a language of the home and social intercourse, and as such enjoys little prestige and is excluded from settings that are considered official or involve people of high rank. For these settings English is used. Further, the educated classes use English as a code together with Cebuano in social settings. Church services that aim at a lower-class audience are in Cebuano, but those aiming at an upper-class congregation are held in English. Books are in English, and English is the official medium of instruction, although for practical reasons teachers make frequent resort to Cebuano at the primary and even secondary levels (the children do not understand English). As an upshot of the emphasis given to English in the educational system and Cebuano's lack of prestige, the elite know the latter but poorly and speak a kind of basic Cebuano mixed with English, which does not make full use of the rich vocabulary and grammatical apparatus which would allow for eloquence. The best knowledge of Cebuano and most eloquent use is on the part of low-status groups, people with little education and little access to English. Cebuano was widely used in mass media until the middle of the 20th century, but in recent years Tagalog has become more and more widespread. There are still radio programs in Cebuano, and there is one weekly, *Bisaya*, distributed throughout the Cebuano-speaking area, which is aimed at a readership with little education.

Cebuano was first recorded in 1521 in a word list written down by Pigafetta, Magellan's chronicler, when Magellan's expedition made its ill-fated stop in Cebu. Catechisms in Cebuano were composed in the years shortly after the first Spanish colonization in 1564, and the translations made at this time are still in use. The earliest dictionaries and grammatical sketches were composed during the 17th century, although none of these were published until the 18th century. Otherwise no literature antedating the 20th century survives, but the beginning of the 20th century saw a surge of interest in Cebuano and the beginnings of a rich literary production, which gradually diminished from the 1920s and 1930s to the point that now very little is being written. The early dictionaries and catechisms of Cebuano show that the language has changed considerably since the 17th century. Many of the verb forms used in the catechisms and cited in the earliest dictionary are no longer used (although remnants are found in rural dialects) and others are confined to ceremonious or particularly fancy styles, and absent from normal speech. In vocabulary, too, the language has changed considerably. At least one-third of the listings in the major Cebuano dictionary by Fr. Juan Felix de la Encarnación, which dates from the middle of the 17th century, were unknown to more than 100 informants queried during the 1960s and 1970s.

What Cebuano Is Like in Comparison with Tagalog

Cebuano is typologically like the other languages of the Philippines, and most similar to Tagalog (*see* **Tagalog**). The sound systems of the two languages are similar, but have a very different rhythm, for two reasons. First, Tagalog loses the glottal stop in any position except before pause, whereas Cebuano pronounces the glottal stop with a sharp clear break, giving a staccato effect to the language. Second, Tagalog has short and long vowels, with no limit on the number of long vowels within a word or on

the syllable on which length occurs. Cebuano has few long vowels, and only on the final syllable. The Tagalog and Cebuano consonant inventories are exactly the same. The vowels are different, however. Cebuano has only three vowels, /i/, /a/, and /u/. (Some dialects retain a fourth central vowel, schwa, inherited from Proto-Austronesian, but this has merged with /u/ in the Cebuano of Cebu City.) The vowels /a/ and /u/ may occur lengthened in the final syllable. Stress is contrastive and occurs on the final or the penult. There can be no more than one long vowel in a word.

The Cebuano verb system is similar to Tagalog's but not commensurate with it: the Cebuano verb expresses tense (action started or not), and also has special tenseless forms which are used when the verb is preceded by an adverb or phrase which expresses tense. These three verb forms are durative or nondurative, as exemplified below:

(1) Action started, punctual vs. action started, durative:
misulʔub siya ug pula
put-on she OBJ red
'she put something red on'
nagsulʔub siya ug pula
is-wearing she OBJ red
'she is (was) wearing something red'

(2) Action not started, punctual vs. durative:
musulub siya ug pula
put-on she OBJ red
'she will put on something red'
magsulʔub siya ug pula
is-wearing she OBJ red
'she will be wearing something red'

(3) Tenseless verb, durative vs. punctual:
waʔ siya musulʔub ug pula
not she put-on OBJ red
'she didn't put something red on'
waʔ siya magsulʔub ug pula
not she is-wearing OBJ red
'she wasn't wearing red'

A system of affixes which show prepositionlike relationships, analogous to that shown by the Tagalog verb, cuts across this tense–aspect system of Cebuano: the Cebuano verbs contain morphemes which express the relation between the verb and a word it refers to. The verb may refer to the agent (active voice), the patient of the action (direct passive), the thing moved or said (conveyance passive), the instrument of the action, the place of the action, the beneficiary of the action, or (peculiarly for Cebuano) time of the action:

(4) (Active)
Mipalit siya ug ságing
bought he/she OBJ bananas
'he **bought** some bananas [that's what he did]'

(5) (Patient)
Gipalit níya ang ságing
bought-it by-him the bananas
'he **bought** the bananas [that's what happened to the bananas]'

(6) (Place)
bálik ta sa **gipalitan**
let's-go-back we to was-bought-at
nímu ug ságing
by-you OBJ bananas
'let's go back to **the place** you **bought** some bananas'

(7) (Instrument)
Maʔu na y
is-the-one that the-one-that
ipalit nímu ug ságing
will-buy-with-it by-you OBJ bananas
'that is the thing [money] you **will use to buy** bananas **with**'

(8) (Beneficiary)
Putling Maríya **igʔampuʔ** mu kami
Virgin Mary pray-for by-you us
'Virgin Mary **pray for** us'

These verbal inflections are added to roots. In addition, new stems can be formed by adding one or more derivational affixes that have meanings similar to those found in Tagalog (*see* **Tagalog**).

Cebuano has a complex system of deictics and demonstrative pronouns that is a good deal more complex than that of Tagalog. The deictics in Cebuano distinguish tense when initial in the clause: e.g., *dinhi* 'was here', *niʔa* 'is here', *anhi* 'will be here.' They distinguish for four distances, *diʔa* 'is here near me (but not near you)', *niʔa* 'is here (near you and me)', *náʔa* 'is there (near you but not near me)', *túʔa* 'is there (far from both of us)'. When final in the clause the deictics distinguish motion from nonmotion: *didtu* 'there (far away)', *ngadtu* 'going there (far away)'. The interrogatives forms for 'when' and 'where' also distinguish tense.

The changes that Cebuano has undergone since the earliest attestations amount to the loss of distinctions. This can be accounted for partly by the fact that Cebuano has been brought to new areas and spread to populations formerly speaking other languages and also by the fact that there has never been a prescriptive tradition which derogates deviant forms. The four-vowel system, which Cebuano inherited from the protolanguage, has been reduced to

three, except in the case of rural dialects. Further, the category durative vs. punctual, which characterizes the verbal system, has in historical times been lost in the passive verbs except in ceremonial styles. Many of the derivational affixes forming verb stems that were productive in pre-19th-century attestations of the language are now confined to petrified forms. In the past two generations Tagalog has influenced an important component of the verbal system, namely, the loss of the tenseless forms, although in rural speech this part of the system is still intact. Further, the system of deictics has been simplified in speakers influenced by Tagalog: namely, tense has been lost, the four-way distance distinction has been reduced to two – i.e., 'here' vs. 'there,' and the distinction between deictics expressing motion and those which do not has been lost. These changes are most strongly observed in areas which or among groups who have contact with Tagalog speech, and from this population these simplifications spread elsewhere in the Cebuano speech community.

Cebuano morphology differs in type of Tagalog in two ways: first, affixational patterns are regular and predictable in Tagalog but in Cebuano they are not: whereas in Tagalog the paradigms are normally filled out for all roots with a given meaning type, in Cebuano many affixes are capriciously distributed, quite irrespective of the semantic qualities of the root. Second, there are numerous variations in affixation and some of the interrogatives, distributed by areas and individual speakers. Tagalog has much less variation.

Celtic

C Ó Baoill, University of Aberdeen, Aberdeen, UK

© 2006 Elsevier Ltd. All rights reserved.

The Celts get their name from *Keltoi*, a name of unknown origin applied by the Greeks from around 500 B.C. to a widespread people who lived mainly to the north and west of them. They have long been identified with the archaeological cultures known as Hallstatt and La Tène, named from type-sites in central Europe and dating from the period following 600 B.C., but linking a language to an archaeological culture can be unreliable, and this link and others concerned with the Celts have been queried, notably in James (1999).

The languages understood to belong to these people are of the Indo-European family, the most westerly branch of it, and one important feature thought to mark Celtic out from the rest is the loss (or reduction in some contexts) of the letter *p*. For example, the Indo-European word for a 'father,' which began with *p*- (whence, e.g., Greek and Latin *pater*), gives modern Gaelic (Gaelic, Irish) *athair.* This development predates all the evidence we have for the languages. Another early development was the change in some branches of Celtic, whereby the Indo-European /k^{u}/ (or 'Q') became /p/, whence the well-known division between P-Celtic and Q-Celtic languages. In the later (insular Q-Celtic) languages this *q* has developed to a /k/ sound, written *c*, and so we get oppositions like Gaelic *cenn* and Welsh *pen*, 'head' (from an original stem **qen*-).

The languages may be classified as Continental Celtic and Insular Celtic, the former group dating from the earliest period of Celtic history up till about 500 A.D., by which time all the continental languages had probably disappeared. Three main continental languages are identifiable, Gaulish, Lepontic, and Celtiberian, and we know all three principally from inscriptions (on stones or on coins),

Celtic

C Ó Baoill, University of Aberdeen, Aberdeen, UK

© 2006 Elsevier Ltd. All rights reserved.

The Celts get their name from *Keltoi*, a name of unknown origin applied by the Greeks from around 500 B.C. to a widespread people who lived mainly to the north and west of them. They have long been identified with the archaeological cultures known as Hallstatt and La Tène, named from type-sites in central Europe and dating from the period following 600 B.C., but linking a language to an archaeological culture can be unreliable, and this link and others concerned with the Celts have been queried, notably in James (1999).

The languages understood to belong to these people are of the Indo-European family, the most westerly branch of it, and one important feature thought to mark Celtic out from the rest is the loss (or reduction in some contexts) of the letter *p*. For example, the Indo-European word for a 'father,' which began with *p*- (whence, e.g., Greek and Latin *pater*), gives modern Gaelic (Gaelic, Irish) *athair.* This development predates all the evidence we have for the languages. Another early development was the change in some branches of Celtic, whereby the Indo-European /k^{u}/ (or 'Q') became /p/, whence the well-known division between P-Celtic and Q-Celtic languages. In the later (insular Q-Celtic) languages this *q* has developed to a /k/ sound, written *c*, and so we get oppositions like Gaelic *cenn* and Welsh *pen*, 'head' (from an original stem **qen*-).

The languages may be classified as Continental Celtic and Insular Celtic, the former group dating from the earliest period of Celtic history up till about 500 A.D., by which time all the continental languages had probably disappeared. Three main continental languages are identifiable, Gaulish, Lepontic, and Celtiberian, and we know all three principally from inscriptions (on stones or on coins),

names (place-names and personal names) and quotations on record in other languages. Verbs, and therefore sentences, are extremely rare, so that our knowledge of all three languages really is minimal. Gaulish and Lepontic are P-Celtic languages, the former belonging to the general area of Gaul (France, but including also parts of Switzerland, Belgium, and Italy) and the latter to parts of the southern Alps. Celtiberian is the name favored, over the alternative Hispano-Celtic, by de Hoz (1988) for the Q-Celtic language, which has, since the mid-20th century, come to be reasonably well attested by inscriptions in north central Spain; a relevant opposition here is between the form used for 'and' (Latin *-que*), appearing as *pe* in Lepontic and as *cue* in Celtiberian.

Archaeology indicates movement of features of the Hallstatt and La Tène cultures from the continent to Britain and Ireland from about 500 B.C., and it is assumed that Celtic languages came with them. Jackson (1953: 4) used the term Gallo-Brittonic to cover both Gaulish and the first P-Celtic languages in Britain. A Q-Celtic language appeared in Ireland, but there is much disagreement as to when, whence, and by what route. There is also much discussion of criteria for assessing relationships between the Celtic languages in this early period, and opinions change frequently (see Evans, 1995); evidence for dating expansion and change in the languages is inevitably scarce.

The Insular Celtic languages are divided into Brythonic and Goidelic groups, the former denoting the descendants of the P-Celtic, which reached Britain from the continent, namely Welsh, Cornish, Breton, Pictish, and Cumbric. Cumbric (or Cumbrian) is used to denote the early language(s) of what are now the northern part of England and the southern part of Scotland, but little is really known about the language(s) apart from what can be gathered from names (see Price 1984: 146–154). The surviving languages in the Brythonic group are Welsh and Breton, Cornish having gone out of general use in the 18th century, though it is still in use among enthusiasts. Sims-Williams (1990: 260; see also Russell, 1995: 132–134) argued that the main linguistic developments from (the theoretical) Brittonic, leading toward the modern insular languages, were in place by 500 A.D., and divergences between Cornish and Breton followed shortly afterward.

Goidelic is the term used by linguists for the Q-Celtic language that appeared in Ireland before the 1st century B.C. and for its descendants. The theory has long been that the original Goidelic language in Ireland spread to western Britain when the power of the Romans waned around 400 A.D., and that Scottish Gaelic (Gaelic, Scots) and Manx eventually developed there. But while the simple theory of a major Irish migration bringing Gaelic to Scotland is widely accepted, even in Scotland, Ewan Campbell has recently shown (Campbell, 2001) that archaeology provides no evidence in support of any such invasion.

The earliest written form of the Gaelic language is that found in Ogam, the alphabet used for inscriptions on stone, dating from about the 4th century till the 7th (McManus, 1991 is a detailed study). Thereafter the language, as attested in the literature, is divided into Old (till 900 A.D.), Middle (900–1200), Early Modern (till *c.* 1650), and Modern periods. The distinctive Scottish and Manx forms only become clearly visible in the Early Modern period. The linguistic theory in Jackson (1951: 78–93) envisaged a historical period, *c.* 1000–1300 A.D., during which Irish (as Western Gaelic) became clearly distinct from Eastern Gaelic (Scottish Gaelic and Manx), but this has come under attack by those (such as Ó Buachalla, 2002) who see the significant historical division within Goidelic as a north/south one, with Scotland, Man, and Ulster in opposition to the rest of Ireland on many points.

On similar grounds, the three Gaelic languages may be seen rather as what Hockett (1958: 323–325) called an L-complex, a single linguistic continuum within which national and even geographical boundaries are ignored by dialectal isoglosses. This suggestion (cf. Ó Buachalla, 1977: 95–96) is supported (a) by the fact that all three 'languages' identify themselves by variants of the same name, *Gaeilge*, *Gàidhlig*, *Gaelck,* and others, whence the English term Gaelic; and (b) by the strong evidence that, while Gaelic survived (until the early 20th century) in the interface area between north-eastern Ireland and the southern Highlands, speakers on both sides of the North Channel were able to converse with little difficulty.

Celtic Religion

B Maier, University of Aberdeen, Abderdeen, UK

© 2006 Elsevier Ltd. All rights reserved.

This is used as a convenient umbrella term to refer to the religious beliefs, myths, rites, and cults of all the Celtic-speaking peoples before the advent of Christianity. The designation *Celtic* may be justified on linguistic, archaeological, and historical grounds, but it should be noted that these criteria do not always converge. Moreover, one might just as well talk of Celtic religions (in the plural), as there are marked regional and chronological differences in a continuum that stretches from Ireland to Asia Minor and from the 5th century B.C. to the 5th century A.D. What we know about Celtic religion is mainly based on archaeological findings, information provided by Greek and Roman authors, and inferences drawn from the medieval vernacular traditions of the Celtic-speaking countries. On this evidence, it is assumed that the Celts worshipped a multitude of gods and goddesses, but the names of these are known only from the Roman imperial period onwards. Classical authors and Latin dedicatory inscriptions from Gaul and Britain usually equate Celtic deities with their Roman counterparts, whereas medieval Irish and Welsh texts tend to treat them on the principle of Euhemerism as mortal beings who were supposed to have lived in a distant past. To judge from the inscriptions, most of the Celtic deities appear to have been of purely local or regional significance. As there are hardly any consecutive Celtic texts from the pagan period, we are ignorant of many basic features of Celtic religion. It is to be stressed, however, that several popular ideas about Celtic religion such as the concept of a 'Celtic calendar' or the belief in a subterranean 'otherworld' are based exclusively on medieval and modern insular sources and should not be projected back on the Continental Celts of classical antiquity. Recent archaeological investigations have provided ample information on pre-Roman cult sites and sacrificial practices, but the well-known Celtic priesthood of the druids continues to be known from literary sources only. Here the most detailed information is provided by the Stoic philosopher Posidonius and by Julius Caesar, but the different pieces of information provided by these two authors are sometimes contradictory and generally cannot be verified by reference to other, independent witnesses. Druids are also mentioned in medieval Irish works of literature set in the pre-Christian period, but the descriptions given of them appear to be modeled on that of Christian priests, so that their source value for the history of Religions appears rather limited.

Central African Republic: Language Situation

C Thornell, Göteborg University, Göteborg, Sweden

© 2006 Elsevier Ltd. All rights reserved.

The Central African Republic, with a population of 3.7 million people (annual growth rate = 1.56%), is multilingual, as most of the African countries are (Figure 1). As a rule, urban centers are multilingual, whereas rural areas are more or less monolingual. The language of the dominant ethnic group prevails. For the past decades, contact between urban centers and rural areas has increased, which has resulted in more than one language being used in rural areas. In particular, this is the case in places in which economic activities are going on. In this multilingual setting, French and the Central African language Sango have the status of official languages.

The number of languages spoken in the Central African Republic is not clear. The figures vary between sources. The *Atlas linguistique de L'Afrique centrale: Centrafrique* (ALC), published in 1984, indicates 43 languages, whereas Ethnologue in 2000 mentions 69. One reason for the variance is that different definitions of the term 'language' are used. The individual languages included in these numbers are, in general, associated with ethnic groups and subgroups, which traditionally are found in specific geographical areas. Thus, the languages are not defined according to linguistic criteria. From a linguistic point of view, it would in many cases be more appropriate to speak about dialect clusters instead of languages (Figure 2).

Language Classification

The Central African languages are classified to the Niger-Congo, the Nilo-Saharan, and the Afro-Asiatic phyla (Figure 3). A small number, spoken in the northern and eastern part of the country, is grouped into the Nilo-Saharan phylum (i.e., Runga and Sara, and the Afro-Asiatic languages include Hausa and Arabic. Most national languages are affiliated to the Niger-Congo phylum. More precisely, they belong to the subgroups of the Ubangi and Bantu languages. The Ubangi languages dominate both in terms of number of languages and of speakers. Important clusters include:

1. The Gbaya cluster, including Manza: mainly spoken by the Gbaya people either as a mother tongue or a second language. The Gbaya live in the western part of the country, and the number of Gbaya is estimated at 30% of the total Central African Republic population (1996).
2. The Banda cluster: spoken by people belonging to the Banda groups. These people inhabit the central parts of the country, and they include about 20% of the Central African Republic population.
3. The Ngbandi cluster, with its main dialects Sango Riverain, Yakoma, and Dendi: The dialects are predominantly spoken by the Ngbandi ethnic group, which lives along the Ubangi River. The group represents about 5% of the Central African Republic population. The official language, Sango, is also classified as belonging to the Ngbandi cluster, although the language originates as a pidgin. The language came into being in the nineteenth century as a trade language. Today, it has the character of an extended pidgin/creole language. Its core vocabulary, and parts of its peripheral vocabulary as well, come from the Ngbandi cluster, other Ubangi languages, and Bantu languages. Concepts typical of Western civilization have been encoded in French words, but the grammatical structures developed out the languages of the area. All Central Africans except 11% have at least some proficiency in the language, according to the 1988 census. Approximately 10% of the inhabitants of the Central African Republic speak Sango as their mother tongue.
4. The Zande-Nzakara cluster: spoken by the Zande and Nzakara peoples, who reside along the Mbomou River. Ethnologue also includes the Kpatili variety in the Zande-Nzakara cluster. This variety could also be included in the Ngbandi cluster. The Zande and Nzakara peoples are estimated to make up 3% of the Central African Republic population.

The other subgroup of the Niger-Congo phylum, the Bantu languages, is represented by small languages, such as Mpiemo and Pande, spoken in the southwestern part of the country.

There are also varieties that can be characterized as mixings. For instance, Yangere-Gbaya, spoken south of Bania in the southwest, has emerged out of both

Figure 1 Location of the Central African Republic.

Figure 2 Language map of the Central African Republic, adapted from *Atlas linguistique de L'Afrique centrale: Centrafrique* (1984).

the Gbaya dialect spoken in the area and Yangere, belonging to the Banda cluster.

In addition to Sango, there are lingua francas used at the regional level, such as Gbaya-Biyanda used in the southwestern part of the country and Zande in the eastern part of the country.

Language Policy

The governments in power since the Central African Republic achieved independence in 1960 have kept the former colonial language, French, as official language, but the Sango language has successively been promoted. In 1964, it was declared the only national language, and in 1991 it was declared an official language alongside French. Having the status of a national language, Sango was an important unifying symbol in the building of the independent Central African Republic. Simultaneously with the promotion of Sango as an official language in 1991, the other Central African languages received the status of national languages. This meant that they became recognized by the government which they have not been earlier. They were now allowed to be used in some formal domains, such as at the lower administration levels.

Measures for Sango to function optimally as an official language have been taken. The institution mainly responsible for these matters is the Institut de Linguistique Appliquée in Bangui. An orthography has been elaborated, and a terminology adapted to a modern society has been successively elaborated. In the making of terminology, a purist approach is applied, which implies that the Sango lexical stock and Sango's capacity for word formation are widely used for the creation of new words. French borrowings are avoided, and established French loan words are replaced. A further step in implementing Sango as an official language is the translation into Sango of the constitution, the laws, and government documents, which hitherto have all been in French. In addition, other Central African languages, mainly used in oral communication, are now subject to language-planning activities in terms of elaboration of orthographies, dictionary compilations, and grammar writings based on linguistic research. These languages are focused on by the Association Centrafricaine de Traductions de la Bible et de l'Alphabétisation and SIL International.

Language Use

Despite the language policy determining which language must to be used in formal domains, language use in many situations depends on the speakers' language proficiency. Sango is more and more being

Figure 3 Figure classification of the Central African languages, adapted from ALC (1984).

used at the expense of French. French is mostly used at higher levels of administration, in the media, and at school. Nevertheless, French is still considered to be the more prestigious language. The increasing use of Sango is also occurring at the expense of the other national languages, which in the long run will lead to a country-wide language shift to Sango.

Executive Domain

In the executive domain, the two official languages are used. In the legislative domain, for instance, the National Assembly holds some of its sessions in Sango. In the provinces, Sango is used in situations in which French has traditionally been used, such as in speeches by government officials. In jurisdiction, some laws, such as 98.004 on 27 March 1998 on the electoral code of the country, exist in Sango, and the remainder of the laws are on their way to be translated. In courts, Sango is used when the defendants do not know French, and translation into national languages is given when needed. The traditional leaders, in their role as state representatives, often speak in a national language, or Sango, in their official communications. In international contacts, however, French has been the undisputed language, though today English is a competing alternative.

School

French is the medium of instruction and learning in school at all levels despite the 1984 decree stipulating that instruction should be given in Sango as well. For the time being, explanations in Sango are allowed in

lower grades when needed. Although it is said that other Central African languages are not used for these explanations, they probably are, particularly in rural areas.

Despite primary school being compulsory, less then half the children (males, 47%, and females, 39%) attended primary school, and only 24% of these reached grade 5 according to Central African administration data (UNICEF). The enrolment rate is high in the capital and low in the country's rural areas. Approximately half of the adult population was literate (51%) in 2003 (world Fact-book, 2005).

Proficiency in French and length of school attendance, both in urban and rural areas, are related, because it is in school that students get their greatest exposure to French. This means that more people in urban areas tend to have proficiency in French than in rural areas.

Media and Literature

The state broadcasting company 'Radio Bangui,' which does both radio and TV broadcasts most radio programs in Sango (70%) and the rest in French. French-speaking people frequently listen to international radio channels in French. The television programs shown by Radio Bangui are mainly in French. Programs from abroad are also accessible via satellite dishes, and most of these programs, which are shown to the public by private persons, are in French.

In the capital, people have access to the Internet. There is even a home page in Sango (http://sango.free.fr), of which Marcel Diki-Kidiri at CNRS in Paris is the webmaster. Central African journalists broadcasting in Sango tend to use new terminology, which sometimes makes understanding difficult for common people.

Central African writers write in French and publish in France. An example is Etienne Goyémidé, who published his book *Le silence de la forêt* at the publishing house Hatier, in Paris (1984). Most literature and printed material in the country comprises translations from either English or French and published by religious denominations. The major part of the literature is in Sango, but in recent years printed materials in other Central African languages have been published. Muslims read publications in Arabic, imported from Muslim countries. One reason for the low production of printed materials is that the demand is low – oral communication is much more important.

Religious Activities

Religious activities play an important role in the Central African society because half the population is Christian and 15% are Islamic. In Christian services, Sango is the common language, although a revitalization of national languages is taking place. Moreover, the mixing of languages is not rare in services, nor are translations, such as of the sermon into the dominant national language of the area. In urban areas, services are held in French, and in the capital they are even held in English. The Muslim services are in Arabic, and in some cases explanations are made in Sango or a national language.

Communication in Everyday Life

The language used in the daily life depends on the situation. In a predominantly monolingual geographical area, the national language of the area is, for obvious reasons, used in most domains. Only in communication with visitors who do not know the national language in question is another language, which in many cases today would mean Sango or a regional lingua franca, used.

In a multilingual area, the use of national languages is roughly limited to communication with people belonging to the same speech community. In other situations, Sango, and to a lesser extent the other official language, French, are commonly used. Even within families in which the parents belong to the same ethnic group Sango may be spoken. It is not rare that the parents speak to them in their national language and get the answer in Sango. In these cases, the children understand but do not speak the national language. Between themselves, they always speak Sango.

In everyday conversations, switching between languages is a frequent phenomenon, at the phrase level and beyond. For instance, people speaking Sango and national languages switch very often into French. Furthermore, they frequently use French loan words. This means that people in everyday life speak a Sango variety that differs from the variety modeled by the language-planning institutions, in that this latter variety is free from French expressions.

Central Solomon Languages

A Terrill, Max Planck Institute for Psycholinguistics, Nijmegen, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

There are four or possibly five Papuan languages in the central Solomon Islands: Bilua, spoken on the island of Vella Lavella; Touo (known more commonly in the literature as Baniata, after one of the villages where it is spoken), spoken on Rendova Island; Lavukaleve, spoken in the Russell Islands; Savosavo, spoken on Savo Island; and possibly Kazukuru, an extinct and barely documented language of New Georgia.

Relationships Among the Languages

By the time of Ray (1926, 1928), there was already an established list of non-Austronesian languages of the Solomon Islands, consisting of Bilua, Baniata (here referred to as Touo), Savo, and Laumbe (now called Lavukaleve). Waterhouse and Ray (1931) later

There are four or possibly five Papuan languages in the central Solomon Islands: Bilua, spoken on the island of Vella Lavella; Touo (known more commonly in the literature as Baniata, after one of the villages where it is spoken), spoken on Rendova Island; Lavukaleve, spoken in the Russell Islands; Savosavo, spoken on Savo Island; and possibly Kazukuru, an extinct and barely documented language of New Georgia.

Relationships Among the Languages

By the time of Ray (1926, 1928), there was already an established list of non-Austronesian languages of the Solomon Islands, consisting of Bilua, Baniata (here referred to as Touo), Savo, and Laumbe (now called Lavukaleve). Waterhouse and Ray (1931) later

discovered Kazukuru, a language of New Georgia, identifying it as unlike both the Melanesian (i.e., Austronesian) and Papuan languages of the Solomon Islands. Much later, Lanyon-Orgill (1953) claimed Kazukuru and two further varieties, Guliguli and Dororo, to be Papuan languages; however, the data are so scant as to make classification uncertain.

Greenberg (1971) was the first to make an explicit claim for the genetic unity of these languages, as part of his Indo-Pacific family. This claim was shortly followed by Wurm's (1972, 1975, 1982) proposal of an East Papuan phylum, linking all the Papuan languages of the islands off the coast of New Guinea into one genetic grouping. Both claims have been firmly rejected by specialists in the region, and recent views have been much more cautious: Ross (2001) suggested, on the basis of similarities in pronouns, that Bilua, Touo (Baniata), Savosavo, and Lavukaleve formed a family, unrelated to other island and mainland Papuan languages. Terrill (2002) found limited evidence of similarities in gender morphology among these languages. In lexical comparisons using an extended Swadesh list of roughly 333 items (with obvious Austronesian loans removed), Bilua, Lavukaleve, Touo, and Savosavo share only 3–5% resemblant forms (i.e., within the realm of chance). In short, at this stage of knowledge, a genetic relationship among any or all of these languages still remains to be proven.

Typological Characteristics

A typological overview of these and other Papuan languages of island Melanesia provided by Dunn *et al.* (2002) showed that, but for a few striking exceptions, the only grammatical features shared by the central Solomon Islands Papuan languages are also held in common with surrounding Oceanic Austronesian languages. These common features include an inclusive/exclusive distinction in pronouns, dual number (actually, there are four number categories in Touo), reduplication for various purposes, nominative/accusative alignment (although Lavukaleve has ergative/absolutive alignment in certain types of subordinate clauses), and serial verb constructions (absent in Bilua).

The two most notable departures from Oceanic grammatical patterns are SOV constituent order in three of the languages (Bilua has SVO with some variation) and the presence of gender; there are three genders in Lavukaleve, four in Touo, and two in Bilua and Savosavo. Gender in Bilua is contextually determined: the masculine–feminine distinction applies only to human nouns, but for inanimate nouns there is a distinction, marked by the same morphology as marks gender in human nouns, between 'singulative' (=masculine) and 'unspecified number' (=feminine) (Obata, 2003). Savosavo has two genders, masculine and feminine, and it is not clear whether they are contextually determined as in Bilua or permanently assigned as in Touo and Lavukaleve (Todd, 1975).

Touo has some very unusual features for the region, including a phonological distinction between breathy/creaky vs. modal vowels, as well as six vowel positions instead of the usual five for the region. Touo sources include Todd (1975), Frahm (1999), and Terrill and Dunn (2003). Lavukaleve too has many unusual features, including focus markers that show agreement in person, gender, and number of the head of the constituent on which they mark focus; and a very complex participant marking system depending on factors to do with predicate type and clause type (Terrill, 2003).

Čeremisina, Maja Ivanovna (b. 1924)

O Molchanova, Uniwersytet Szczecinski, Szczecin, Poland

© 2006 Elsevier Ltd. All rights reserved.

Maja Ivanovna Čeremisina was born in Kiev (the Ukrainian republic) in 1924. She is a Russian scholar who, after Ubrjatov's death in Novosibirsk, took on the responsibility of continuing research on the syntax of Siberian indigenous peoples' languages. Under her guidance, 33 scholars have investigated the syntactic structures of their mother tongues (Altai, Alutor, Buryat (Buriat), Kazakh, Ket, Khakas, Khanty, Kirghiz, Nganasan, Selkup, Shor, Tuva (Tuvin), and others). Most of them have undertaken 3-year postgraduate courses at the university in Novosibirsk.

Čeremisina received her secondary and higher education in Moscow. Her first years after secondary school were during World War II. On the first day of aerial bombardment in Moscow, her parents' house was completely destroyed, and her mother was killed.

Much later, Čeremisina was educated at the University of Moscow, where she mastered literature and the Russian language and later undertook 3-year postgraduate courses at Moscow University. After graduation, she taught many subjects in Russian philology at university departments in Tomsk, Tula, Beijing (China), and Novosibirsk. Čeremisina obtained her M.A. in 1960 and her Ph.D. In 1974. Her doctoral thesis was entitled 'Complex comparative constructions in the Russian language.' Before Čeremisina's doctoral defense, Ubrjatova asked her to read the manuscript of a book devoted to the analysis of complex sentences in the Yakut language. Čeremisina read the manuscript three times, trying to comprehend Yakut, the frame of mind of its speakers, and their way of expressing themselves, and also trying to penetrate into Ubrjatova's way of thinking, which gradually opened itself up to her. Her main field of endeavor thereafter became Siberian indigenous languages.

In 1975, Čeremisina took charge of a project based on comparative and typological research into the structure of complex sentences in the languages of Siberian indigenous peoples. The starting point of the investigation was one of the postulates propounded by Ubrjatova in her monograph on Yakut syntax – that Turkic languages employ similar language means to establish links between both words and units of higher levels (phrases and sentences). Testing the postulate on other Altaic languages became the goal of Čeremisina and her disciples.

Čeremisina founded a new Department of Languages and Folklore of the Indigenous Siberian Peoples at the university in Novosibirsk.

At present, Čeremisina and her team are working at the typology of a simple sentence in Altaic languages. She has published five monographs, nine textbooks, and 183 papers.

18th Century Linguistic Thought

G Haßler, University of Potsdam, Potsdam, Germany

© 2006 Elsevier Ltd. All rights reserved.

The 18th century has been characterized as a century of debate on language, leading to the formation of new conceptions in this field. The focus on language has also been supported by the role of public opinion and by profound changes in society. But the most important discussions were about the role of language in thought. In the field of language description, 18th-century authors followed for the most part traditional views and contributed to their further development.

Discussions on Language in the Early 18th Century

The inclusion of language in the philosophical systems of Rene Descartes (1596–1650), Antoine Arnauld (1612–1694), and Baruch de Spinoza (1632–1677) was based on the supposition that there was an analogy between the dualism of language and thought and that of body and mind. The basis of the doctrine, which supposed an incorporeal thinking no longer accessible to humans after original sin, had already been developed by St Augustine (354–430). From a historical perspective, thinking required signs to render collections of simple ideas, as well as memory, possible. Signs gave rise to the manipulation of ideas, and they did not depend on the presence of things or the enumeration of all the simple ideas included in them.

A main tenet of the Augustinian–rationalist doctrine was the merely spiritual nature of all notions and of the relations between them. The denotation of a term was regarded as a mental object that could only have a representational relation to the word and could not depend on linguistic signs and their corporeal nature. The form words obtained in different languages was regarded as arbitrary, whereas the composition of the concept was universal and did not depend on sensations. For the rationalist thinkers, the indispensability of language consisted only in communication between people when the transmission of pure incorporeal notions was impossible. But linguistic signs met the necessities of communication in a very insufficient way because intuitive conceptions overwhelmed the human mind while their linguistic signs distracted from their content and slowed down the process of thinking.

Descartes's vision of the relation between language and thought was a dualistic one, in that he did not attribute to linguistic signs any influence on ideas. He saw a confirmation of this opinion in the fact that animals with highly developed speech organs did not develop human thinking even if they were able to produce some speech sounds. This idea was further developed by Gerauld de Cordemoy (1626–1684), who claimed that the substantial difference between language and thought allowed the development of different languages with arbitrary sound patterns.

The authors of the Port-Royal Grammar (1660) and the Logic (1662) took up the distinction between language-independent thought, communicated thought, and language-dependent thinking, and they subordinated linguistic signs to conceptual notions. Had ideas depended on names, people would not have had the same ideas about even the simplest things

because languages use different names to designate them. Arnauld and Pierre Nicole (1625–1695), the authors of the Logic, criticized Thomas Hobbes's (1588–1679) remark that reasoning consisted of comparing names and uniting them by the copula. For the authors of Port-Royal Grammar, human thinking operated with the designated ideas and not with their names. The arbitrariness of the linguistic sign played an important part in this argumentation. The fact that Arabs and French people could communicate proved that thought was independent of language.

But this language-independent thought had to make use of signs if it was to be communicated. The use of signs that restricted to the communication of ideas could become a habit and finally result in a situation where people could no longer imagine ideas without words. For example, many philosophical treatises aimed at satisfying people with words. These arguments led to a critical discussion of language that played an important part in the 18th-century debate.

The diversity of languages had been regarded just as a proof of the secondary role of linguistic signs, but it could not be denied as a practical and an empirical phenomenon that had to be taken into account by grammarians. The contrast between a general way of thinking and the language-specific way of expression was a widely accepted position in 17th- and early-18th-century grammar. A direct linear word order followed most closely by the French language, for example, was declared to be a universal feature. The Latin deviation from this subject–verb–object order was declared to have had no influence on thought; Romans must have thought like French people before they rearranged their ideas using inversions and ponderous constructions (for the debate on word order, see Ricken, 1978).

The existence of different expressions for the same conceptual structure had already been discussed by the grammarians of Port-Royal, who saw no obstacle to universal ideas in it. The system of language at a given moment was always determined by use, and this meant that people had to rely on the elements of their own language, even if they were less developed or less differentiated than in other languages. For example, all languages had to express relations between nouns and whole syntactic units. In languages with case systems these relations were expressed by morphological elements, whereas in French prepositions and word order served the same purpose.

This kind of explanation appeared often in 18th-century grammars, which associated the special genius of a language (*génie de la langue*) with the function of formal elements of language and not with their relation to thoughts. But the notion of a *génie de la langue* had already become very fashionable at the end of the 17th century in systematizations of Vaugelas's *Remarques sur la langue française* by Louis Du Truc (1668), Jean Menudier (1681), and Jean d'Aisy (1685). A temporary pinnacle in the description of the particular means of a language was attained with Claude Buffier's *Grammaire françoise sur un plan nouveau* (1709). According to Buffier, the reality of language disproved the opinion that a grammatical theory must be prior to all languages. In Buffier's view, it was a crucial error to write a French grammar following the principles of Latin. Regarding the signification of words primarily as a function of individual representation, Buffier warned not to confuse signs with designated notions and denied the exact explicability of significations. Following John Locke (1632–1704) in his nominalist positions, he overcame the rationalist theory of language.

The *Essay concerning human understanding* (1690) by Locke gave a new answer to the question of how thought could be influenced by language. According to Locke, linguistic signs did not represent the objects of knowledge but the ideas that the human subject created. The nominalist explanation of complex ideas led to a denial of the existence of innate ideas and to the supposition of a voluntary imposition of signs onto a collection of simple ideas for which there was no pattern in reality.

Universal language had been a tempting issue for a long time. Even Descartes proposed to base his reflections on this matter on the nature of thought and not on actually existing languages. Taking advantage of such a universal language, peasants would be able to think more conveniently than philosophers using any existing language. It was the same idea that led to the *characteristica universalis* by Gottfried Wilhelm Leibniz (1646–1716). His doctrine of the harmonious structure of the world and its perception made him reject the nominalist supposition that signs denoted arbitrarily a collection of simple ideas. The form of signs was not naturally determined but historically motivated and not the result of an arbitrary imposition. Imperfections that could be explained by the nature of language, the fuzziness of significations, the polysemy of words, and the conscious abuse of language, might lead human thinking through a tortuous path. Although in the customary use of language such insufficiency was unavoidable, the philosophical use of language could elude it by creating its own philosophical sign system.

Contradictory Results of Empirical–Sensationalist Thought

The empirical and sensationalist theory of knowledge developed by Locke had a great influence in many

European countries and was taken up in France by César Chesneau de Du Marsais (1676–1756) and Etienne Bonnot de Condillac (1714–1780), among others, whose thoughts led to different conclusions. Du Marsais, in his "Essay on Tropes" (1730), developed a sensationalist theory of metaphor, apart from tackling grammatical issues in his articles in the French *Encyclopédie*. But, in spite of his views on lexical signification rooted in a sensationalist theory, he held a rationalist opinion on syntax, considering subject–verb–object word order as natural and corresponding to the order of thought. However, he modified this theory, recognizing the communicative and stylistic function of different constructions as a counterpart to the figurative use of words.

Du Marsais is an author who is not easily classified as either a sensationalist or a rationalist. Delesalle and Chevalier (1986: 88) have characterized him as building a system of *empirisme raisonné* in which he finally looked for a new strategy of grammatical operations. He tried to deduce a set of principles that would be transferable to new situations from the use of language. Following this concept of analysis, he did not arrive at new conclusions through the application of theorems but by a kind of arithmetic that consisted of composition and decomposition. What were regarded as reliable in this context were not definitions but only explanations of the appearance of an idea. The fundamental attitude about the acquisition of language that stemmed from his theory was routine. Du Marsais's aim was to find an order, a general principle in the multitude of texts. The following example (Du Marsais, 1729/1797: II, 215) shows how a manual of Latin would look following this approach.

Minóis filiam Ariádnen, cujus ope labyrínthi ambáges explicúerat, secum ábstulit: eam tamen, immemor beneficii, deséruit in insulá Naxo: destitútam Bacchus duxit.

ábstulit	secum	Ariádnen,	filiam
il emmena	*avec lui*	*Ariane*,	*fille*
Minóis;	ab	ope cujus	
de Minos	*par*	*le secours de laquelle*	
explicúerat	ambáges	labyrinthi.	
il avoit démélé	*les détours*	*du labirinthe*.	
Tamen,	immemor...		
Cependant,	*ne se ressouvenant point* ...		

'et enleva Ariane, fille de Minos. Cète princesse avoit donné à Thésée un peloton de fil qui aida ce héros à sortir du labirinte. Cependant, oubliant ....'

The first line is the Latin original in all its complexity and with its inversions. The second line shows the Latin sentence transformed into the natural order, and the third and fourth lines show an interlinear translation into French and a current French translation.

It is easy to suspect that such a procedure would be criticized. Du Marsais introduced routine as a basis for the acquisition of language, but what provided this routine? The bad Latin in the second line of our example was certainly not an appropriate means. One of the protagonists of the critical discussion of Du Marsais's method was the Abbé Noël Antoine Pluche (1688–1761), who picked out as a central theme the function of translation in language teaching. Pluche did not reject the use of interlinear translation for the clarification of the structure of the original text when this structure was maintained on the syntactic level. But, for the initial stage of language learning, he rejected translation made on the basis of rules and vocabularies because it would lead to unusual and awkward expressions that were far from the *génie de la langue latine*.

The development of the issue of a *genie de la langue* by Condillac was different in kind. Condillac formulated a coherent sensationalist theory of cognition by substituting for Locke's dualist explication of sensation and reflection the concept of transformed sensation (*sensation transformée*), which helped to explain even complex thought as made up of simple sensations. The instrument allowing this transformation was language, to which Condillac attributed an important role in human thought. Human language arose from a language of gestures (*langage d'action*), which, gradually and stimulated by the needs of communication, developed into a language of arbitrary (artificial) signs. The signs of human language operated according to the principle of analogy, which corresponded to a motivated relation between signs of analogous content. It was this analogy of signs that made up the genius of a language.

The sensationalist discussion of signs and their influence on thought gave rise to several applied themes of discussion (the abuse of words, grammar teaching, construction of a philosophical language, and synonymy). The sensationalist theory was nevertheless only one solution, and it was not generally accepted by all 18th-century language theorists. Authors such as James Harris (1709–1780) continued to suppose the existence of innate powers that produced mental operations such as thinking and reasoning. Although corporeal entities could always be subdivided, the unities of the mind could not. So it was important to discover the elementary principles of the dispositions of the mind that acted in combination. As an important principle for this analysis, Harris (1786/1993: 307) endorsed the distinction between Matter and Form, which he tried to find in language as well:

"Now if Matter and Form are among these Elements, and deserve perhaps to be esteemed as the principal among them, it may not be foreign to the Design of this Treatise, to seek whether these, or any things analogous to them, may be found in Speech or Language." The genius of a language is given an important role in this context: "[...] many words, possessing their Significations (as it were) under the same Compact, unite in constituting a particular Language" (Harris 1786/1993: 328).

For Harris (1786/1993: 398), human cognition did not derive from sensations but from mental archetypes that anticipated perceptible things. All communication consisted for him in the transmission of ideas and words:

> For what is Conversation between Man and Man? – It is a mutual intercourse of Speaking and Hearing. – To the Speaker, it is to teach; to the Hearer, it is to learn. – To the Speaker, it is to descend from Ideas to Words; to the Hearer, it is to ascend from Words to Ideas. – If the Hearer, in this ascent, can arrive at no Ideas, then he said not to understand; if he ascends to Ideas dissimilar and heterogeneous, and then is he said to misunderstand. – What then is requisite, that he may be said to understand? – That he should ascend to certain Ideas, treasured up within himself, correspondent and similar to those within the Speaker. The same may be said of a Writer and a Reader; as when any one reads to-day or tomorrow, or here or in Italy, what Euclid wrote in Greece two thousand years ago.

Another example of a productive survival of rationalist theory in 18th-century grammar is Nicolas Beauzée (1717–1789), who defined general grammar as a science and opposed it to the grammars of particular languages, which he called art. According to him, the rules of scientific grammar should be universal and not depend on the arbitrary properties of languages. The relation of language and thought was explained in a dualistic way: Thought was independent of language, whereas language was an instrument of analysis and at the same time a reflection of thought

Prize Topics on Language Theory

In the second half of the 18th century, the debate on linguistic subjects was especially intense in the Berlin Academy. Several themes were brought for academic competitions and these can be regarded as a reflection of the general European language debate.

Topic I: Relativity and Subjectivity of Languages as a Means of Cognition and Communication

The president of the Academy, Pierre Louis Moreau de Maupertuis (1698–1759) associated the diversity of languages with different forms of thought (*plans d'idées*): Translation among distant languages was considered virtually impossible, and signs had no strict philosophical validity in regard to reality. Reporting in the *Lettre sur le progrès des sciences* (1752) that travelers to the Pacific Islands had seen savages there, Maupertuis concluded that he would rather have an hour's conversation with them than with the most refined mind of Europe. It was also Maupertuis who introduced the origin of language as the topic of an academic prize contest. The signs by which people designated their first ideas, he argued, have so much influence on all our knowledge that research into the origin of languages and the manner in which they were formed deserved as much attention and could be as useful in the study of philosophy as other methods that build systems on words with meanings that had not been thoroughly examined. We might therefore expect to learn a great deal from the comparison of distant languages because in the construction of languages we could discover the vestiges of the first steps taken by the human mind. The diversity of human languages and universals of thought may be regarded as one of the main themes of the discussion. The search for language origins was an attempt to arrive at basic principles, to examine what was natural as opposed to artificial. The empirical reality of the diversity of languages was a challenge to the universalistic principle.

From this challenge arose the question for 1759, whose prize was awarded to an essay submitted by the distinguished Goettingen professor of Semitic languages, Johann David Michaelis (1717–1791). Michaelis's essay, which was translated into English and Dutch after being published in German and French, has become well known in Europe (cf. Michaelis, 1974). Usually only the successful essay was published at the expense of the Academy and all the others were kept as anonymous manuscripts in the archive, but in this case all the texts were published. It is easy to explain why the Academy decided to do this. The relativistic view suggested by the Academy for 1759 was not really taken up, except by Michaelis's prize essay. Obviously, it did not follow the trend of the contemporary language discussion, which was much more occupied with the general foundations of language.

For Michaelis, languages were the results of the work of whole peoples, and this democratic development led to the conservation of prejudices in words. On the other hand, people could contribute to the improvement of languages by the exclusion of etymologies that might mislead human thinking. The French translation contained some important changes suggested by Johann Bernhard Merian

(1723–1807) and André Pierre Le Guay de Prémontval (1716–1764). Michaelis pointed out that no one particular language had a general advantage over others – richness and poverty had always been relative and depended on the purpose that languages were used for. Changes in the text show that there was an attempt to adapt Michaelis's text to the debate, mainly dominated by French texts and terminology. But the chief supplement dealt with the possibility of framing a successful universal language of learning. He now answered a question that had been considered very important by the Academy since the days of Leibniz. In this context, the antiuniversalistic view of Michaelis appears most clearly: A universal language of science would be exposed to even more arbitrary intervention than a natural language because every scientist or philosopher would be able to determine the significations of the words he used (Michaelis, 1762/1974: 167).

Topic II: The Anthropological Foundations and the Origin of Language

If we look at the context of the discussion, it is not difficult to understand why, as early as 1759, the origin of language, and not the philological or philosophical study of different languages, was the fundamental question. In 1756, Jean-Jacques Rousseau's (1712–1778) *Discours sur l'origine et les fondemens de l'inégalité parmi les hommes* was published in German. In the same year, Johann Peter Süßmilch (1707–1767) read two papers on the divine origin of language. Rousseau presented the dilemma succinctly: If people needed speech in order to learn how to think, they must have been in even greater need of thinking in order to invent the art of speaking.

The Academy was interested in the anthropological foundations of language as well as in an explanation of language variety. The question of the origin of language did not aim at historical and factual explanation of previous phases of language development. It was as hypothetical as the state of nature in political philosophy and, like the latter, its aim was to understand people in the present.

But the authors of the 31 papers submitted to the contest did not always respond exactly to the question emphasized by the Academy text. There was, for instance, a manuscript entitled *Rêveries sur le langage* that reduced the problem to the question of whether language was innate or not. Also, without quoting the great texts on the origin of language, many authors just copied them. So we find Condillac's description of the development of human sound language from a language of gestures; traces of this development were to be found in Hebrew, which by its antiquity could be regarded as a natural language. This was another way to empiricize the search for the foundations of language: One of the classical languages, usually Hebrew, was declared to be so close to the origin that it could be regarded as bearing all necessary traces that languages must have.

The issue of another essay (I-667) was the invention of language by human beings. The invention of language was said to be, first of all, due to necessity and danger. If a couple of human beings were exposed to the danger of being devoured by a hungry wolf, the woman, who represented the weaker but more inventive companion, would imitate the wolf's cry to warn her partner. The author discussed 10 simple steps that led from this origin to the present state of development. It is interesting that for the author of this essay there was no essential difference between the structures of different languages. The languages of Greenland, Japan, the Hottentots, the Oronocs, the Tartars, and the Caribbean were regarded as regular and analogous. They expressed the same anthropological foundations as the European languages, in a very simple way, which could be proved by the forms of their inflexions. According to the author, declension, conjugation, and syntax were common features of all languages. This attitude was typical of the kind of hypothetical empiricism used to study language diversity and its consequences or to explain universals without any regard to real languages. The few examples quoted by any author using this kind of hypothetical empiricism were always very close to the everyday experience of the author. In the case of this essay, the author quoted mainly German examples, to which he added some Polish, French, Greek, and Latin ones.

There was also a second kind of hypothetical empiricism, apart from the one we have just discussed. This is obvious in an essay (I-666) that received the accessit by the Academy, written in Latin by Francesco Soave (1743–1806). For the author of this contribution, evidence about the origin of language was to be obtained by observing children who grew up outside society. He repeated a hypothetical experiment already discussed by Bernard de Mandeville (1670–1733), Condillac, and others. Contemporary authors were aware that ethical concerns would never allow them to carry out this experiment. They referred, however, to cases of real savage children who had been found and whose intellectual and communication habits had been studied.

As we have seen, there was a wide range of thinking about the diversity of human languages and its relation to the mental development of humans. Why, in spite of this, has Johann Gottfried Herder (1744–1803) gone down in the annals of history as a so-called forerunner of linguistic relativism? Herder

offered a solution to the main anthropological problem without leaving aside the empirical reality of languages: Endowed with the capacity for thought characteristic of humans and for the first time freely exercising this capacity, humans invented language. The doctrine of the intimate connection between *Volksgeist* and language has generally been regarded as one of Herder's most important contributions to the thought of that age. Nevertheless, it is easy to find such statements on a reciprocal dependency between the genius of the languages and the characters of the peoples in other texts of the language discussion (cf. Haßler, 1984; Neis, 2003).

Linguistic questions were discussed repeatedly with reference to the great 18th-century texts that were published and distributed. This seems to have contributed to a rather monolithic picture of the ideas brought up by the contests. It is quite natural that Jacob Grimm (1785–1863) should refer respectfully to Herder in his own treatise on the origin of language, even though he noted a lack of depth and erudition in the reflections of this author, who could not compete with the scientific view of language imposed by the development of comparative linguistics in the 19th century. In the 19th century, Herder became one of the intellectual heroes of Romanticism. The references to Herder constitute an impressive corpus, which is sufficient to explain the preferences of modern historiographers. His contribution to the classical heritage seems to be evident. But did it really consist in having found out that languages were different and related to human thought, that every language expressed the soul of the people who used it? This idea was much more explicit in the texts of other contributors of the 1771 question. What really made up the outstanding quality of Herder's essay was the fact that he explained the general foundations of language and, in this way, the origin of language.

The papers submitted for the contest on the origin of language show that the authors did not always answer exactly the question that seemed to be important to the Academy. In contrast to the question of 1759, this time the Academy invited them to examine the foundations of language, but many of the contributors wrote about the presumed history of languages and about their differences and grammatical categories.

Topic III: Comparing and Assessing Languages

It is justified to say that the Academy was always a little late, inviting authors to answer questions that had already been under discussion for several years. But in the case of the relative value of languages with respect to communication and thought, the Academy just changed the focus. After having turned from diversity, which was accentuated in 1759, to the anthropological foundations in 1771, it returned to diversity for another question in the last decade of the century: *Vergleichung der Hauptsprachen Europas, lebender und todter, in Bezug auf Reichthum, Regelmäßigkeit, Kraft, Harmonie und andere Vorzüge; in welchen Beziehungen ist die eine der anderen überlegen, welche kommen der Vollkommenheit menschlicher Sprache am nächsten?* (1792–1794).

But the context of the debate had changed. It was the time of the great language collections, which either had already appeared or were under preparation. Nevertheless, it seems to have been difficult to get contributions. In 1792, when the topic was first brought up, only two essays arrived, one of which was by a Goettingen professor who had worked in accordance with the ideas of Michaelis, comparing mainly classical languages. This author asserted that Greek was the ideal language for scientific communication and that German was a poor language that would never be suited to learned purposes. It is evident that this excluded him from winning the prize, especially at a time when the Academy was looking for a substitute for French, which has been in decline since the death of Frederic the Great. The second manuscript has been lost, but a remark by the secretary of the Academy ascribes it to Johann Christoph Schwab (1743–1821), who had shared with Antoine de Rivarol (1753–1801) the prize on the universality of French.

The Academy had to wait 2 more years to receive a contribution that deserved the prize. It was written by the Berlin preacher Daniel Jenisch (1762–1804) and was published in 1796. Jenisch's book has usually been considered as one of the forerunners of 19th-century historical–comparative linguistics. However, it was written in the context of an empiricism that was merely hypothetical. All his considerations about languages are guided by epistemological observations and second-hand testimonies about language facts. He acknowledged this himself, nevertheless feeling a certain need for another kind of empirical studies.

What Jenisch promised was not a philological comparison of languages – in this respect, the competing Goettingen manuscript was much more consistent – but an assessment of languages on the basis of a constructed ideal. This ideal language consisted of the familiar properties found in the Renaissance discussion of language. Richness, lucidity, insistence, certainty, and euphony were such properties, and they were not to be found to the same degree in all languages. Thus, the advantages or disadvantages of any language depended on the purpose and the field the language would be used for. By asserting that

languages were equal in rank and could not be reduced to a universal grammar, Jenisch envisaged an impartial comparison of languages. But his idea of empiricism was merely hypothetical and based on literature.

So the prize-winning topic on the comparison of languages did not prepare or even open a new epoch of language studies but concluded the discussion on universals and the relativity of languages in the context of the Enlightenment debate. At the end of the 18th century, new kinds of empirical questions were emerging, but many authors still tried to address them through the old epistemological framework.

The República de El Salvador is linguistically more Spanish than Spain. Nine tenths of this Spanish-speaking Central American culture is ethnically mestizo (of mixed American and European heritage). Almost none of the resident Amerindians can speak anything but Spanish, which is also the dominant language of most of the European Salvadoreños. Other languages are spoken primarily as foreign languages of cultural and commercial interaction, with the possible exception of some Mayan-speaking immigrants from Guatemala. Spanish usage is so strong that, although knowledge of English is widespread in San Salvador business circles, even foreigners

Čeremisina, Maja Ivanovna (b. 1924)

O Molchanova, Uniwersytet Szczecinski, Szczecin, Poland

© 2006 Elsevier Ltd. All rights reserved.

Maja Ivanovna Čeremisina was born in Kiev (the Ukrainian republic) in 1924. She is a Russian scholar who, after Ubrjatov's death in Novosibirsk, took on the responsibility of continuing research on the syntax of Siberian indigenous peoples' languages. Under her guidance, 33 scholars have investigated the syntactic structures of their mother tongues (Altai, Alutor, Buryat (Buriat), Kazakh, Ket, Khakas, Khanty, Kirghiz, Nganasan, Selkup, Shor, Tuva (Tuvin), and others). Most of them have undertaken 3-year postgraduate courses at the university in Novosibirsk.

Čeremisina received her secondary and higher education in Moscow. Her first years after secondary school were during World War II. On the first day of aerial bombardment in Moscow, her parents' house was completely destroyed, and her mother was killed.

Much later, Čeremisina was educated at the University of Moscow, where she mastered literature and the Russian language and later undertook 3-year postgraduate courses at Moscow University. After graduation, she taught many subjects in Russian philology at university departments in Tomsk, Tula, Beijing (China), and Novosibirsk. Čeremisina obtained her M.A. in 1960 and her Ph.D. In 1974. Her doctoral thesis was entitled 'Complex comparative constructions in the Russian language.' Before Čeremisina's doctoral defense, Ubrjatova asked her to read the manuscript of a book devoted to the analysis of complex sentences in the Yakut language. Čeremisina read the manuscript three times, trying to comprehend Yakut, the frame of mind of its speakers, and their way of expressing themselves, and also trying to penetrate into Ubrjatova's way of thinking, which gradually opened itself up to her. Her main field of endeavor thereafter became Siberian indigenous languages.

In 1975, Čeremisina took charge of a project based on comparative and typological research into the structure of complex sentences in the languages of Siberian indigenous peoples. The starting point of the investigation was one of the postulates propounded by Ubrjatova in her monograph on Yakut syntax – that Turkic languages employ similar language means to establish links between both words and units of higher levels (phrases and sentences). Testing the postulate on other Altaic languages became the goal of Čeremisina and her disciples.

Čeremisina founded a new Department of Languages and Folklore of the Indigenous Siberian Peoples at the university in Novosibirsk.

At present, Čeremisina and her team are working at the typology of a simple sentence in Altaic languages. She has published five monographs, nine textbooks, and 183 papers.

Cerron-Palomino, Rodolfo (b. 1940)

C Parodi, University of California, Los Angeles, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Rodolfo Cerrón-Palomino, an emeritus professor at the Universidad Nacional Mayor de San Marcos, Lima, (1970–1991) and an active professor at the Pontificia Universidad Católica del Perú (1998 to date), is a prominent figure of Andean linguistics.

He received his Bachelor of Arts from the Universidad Nacional Mayor de San Marcos, Lima, and his Masters degree from Cornell University in Lingusitics. Professor Cerrón-Palomino has two Ph.D. degrees in Linguistics, one from Universidad Nacional Mayor de San Marcos, and a second one from the University of Illinois at Urbana Champaign. He was awarded the Gugenheim fellowship, in addition to earning several other honors in Germany, Holland, and the United States.

Cerrón Palomino's linguistic work focuses on the indigenous languages of the Andes: Quechua, Aimara, Chipaya and Mochica. He has researched bilingualism in Peru, the linguistic interference of Spanish into Indian languages, and the influence of Quechua into Spanish. Within the Quechua linguistic family, he has produced historical, sociolinguistic, and descriptive work of several dialects of Central or Junin-Wanka Quechua. He spearheaded the standardization of modern Quechua, which has been implemented in Peruvian rural public schools to provide the students with bilingual education.

Cerrón-Palomino argued against the Quechumara hypothesis championed by Orr and Longacre. He showed that Proto-Quechua and Proto-Aimara are languages that do not share a common origin. His historical work on Quechua continued in his book *Lingüística Quechua* (1987) a broad survey of Quechua geographical distribution, including all the main dialectal variations, origins, development, classification into dialects, phonology, and grammar.

He studied the Aimara linguistic family from Peru, Bolivia, and Chile in his book *Lingüística Aimara* (2000). In his detailed work on Andean languages, he uses colonial sources such as Ludovico Bertonio, Diego Gonçalez Holguin, and Inca Garcilaso de la Vega. In his article *Lenguas de la costa norte peruana* (2004), he sheds light on prehispanic language contact in Peru due to the 'mitmas.' The mitmas were Inca institutions that caused demographic movements of different human linguistic groups along the Inca Empire and that aimed to control newly conquered people. Recently, he has been working with Andean Spanish and Chipaya, the only language alive of the Uru family.

In his book on Andean Spanish, *Castellano andino* (2003), he addresses the variation of rural Spanish due to the interference of Quechua and Aimara bilingualism in Peru. He exposes the prejudice the speakers of Andean Spanish have to face, since their speech, called 'motoso Spanish,' is highly stigmatized. Andean Spanish has a noncanonical word order and different agreement patterns than standard Spanish. In addition, Andean Spanish incorporates Quechua and Aimara loanwords that are not used in standard Peruvian Spanish. Cerrón-Palomino traces the origins of Andean Spanish in colonial texts, such as in Guamam Poma's *El primer nueva coronica y buen gobierno*. He has also analyzed Quechua loanwords into local Peruvian Spanish and loanwords of Spanish into Quechua.

Cerulli, Enrico (1898–1988)

P D Fallon, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Enrico Cerulli, born on February 15, 1898 in Naples, was a diplomat, anthropologist, and linguist who specialized in the languages, history, and cultures of Ethiopia, Somalia, and Eritrea.

After attending the University of Naples and earning a law degree, in 1920 Cerulli began an impressive diplomatic career. He became Secretary and later Director of Political Affairs in Italian Somaliland from 1920 to 1925. A Counselor for the Italian Legation to Ethiopia from 1926 to 1929, Cerulli also participated in an exploratory trip to Western Ethiopia and a scientific expedition to the sources of the Wabē Shabelē River. He was the Italian representative to the Anglo-Italian Boundary Commission for Somaliland (1930–1931). He became the Secretary-General of the Ministry for Italian Africa from 1932 to 1935, then a delegate to the League of Nations (1935–1937). He married Lina Ciotola in 1936 and had two sons with her.

Favored by Mussolini, Cerulli was appointed Deputy Governor-General of Italian East Africa in 1938. Cerulli is widely recognized as a scholar of considerable repute. Yet Bahru (2001: 162) has cited Cerulli as "the perfect example of scholarship being put at the service of colonial administration." Sbacchi (1985) wrote that many Italians in Africa thought that Cerulli was incapable of carrying out responsibilities of high office and that he favored Somalis over other ethnic groups. Yet he was one of only a few officials with extensive colonial experience, and he was highly knowledgeable about the local environment. Because of incompatibility with the Governor-General, the Duke of Aosta, he was transferred to Harar as Governor. Cerulli retired from public service (1940–1944). Later, he was an Italian delegate to the Peace Conference (1944–1947), the Four-Power Conferences in London from 1947 to 1949, and delegate to the United Nations regarding Italian African Territories. From 1950 to 1954 he was ambassador to Iran, and from 1955 to 1968 he was Councilor of State.

Cerulli wrote many grammatical sketches (based on fieldwork) on languages around the Horn of Africa, including Harari (Ethiopian Semitic); Somali, Sidamo, Arbore, Komso, and Daasanach (Cushitic); Janjero (Yemsa), Chara, Basketto, and Koorete (Omotic); and Berta (Nilo-Saharan). Some of these works were the first linguistic documentation of the languages and are generally quite accurate and useful to this day. In addition, Cerulli showed great interest in Somali poetry and songs.

Islam was a driving interest of Cerulli's, from his university studies through his later writings on Islamic connections to medieval Western culture (1949) and Islam in general (1971). Yet Cerulli was also interested in Ethiopian Christianity, its links to Eastern Christianity in Palestine, and its Ge'ez texts on Ethiopian saints.

Cerulli received honorary doctorates from the Universities of Brussels, Rome, and Manchester. He was a member of many academies and societies in Europe, including the Accademia Nazionale dei Lincei (also its Vice-President). He served as President of the Italian Anthropological Institute.

Cerulli was a "man of science and a man of action" (Ricci, 1990) who successfully combined two careers in public service and in scholarship. Cerulli died on September 19, 1988 in Rome.

Chad: Language Situation

J Roberts, SIL-Chad and Université de N'Djaména, Chad

© 2006 Elsevier Ltd. All rights reserved.

Introduction and History

The Republic of Chad is located in the Sahel of north-central Africa, at the meeting place of three of the four major phyla of African languages. As a result, Chad is characterized by great linguistic variety. Today Chad is a checkerboard of numerous language groups, most of them small and each of which is located in a limited geographic area (see **Appendix 1**). The *Ethnologue* (Gordon, 2004) lists a total of 131 living languages in Chad. Only 21 of these languages boast more than 100 000 speakers (see Table 1); nonetheless, these 21 represent about three-fourths of the population of Chad, which current estimates place at about 9 million. More than 50 Chadian languages, on the other hand, have fewer than 10 000 speakers.

The present linguistic situation is the result of movements of peoples, contact between ethnic groups, and the dominance of certain ethnic groups over the centuries. Most of Chad's peoples claim to have come from northeastern Africa or the Middle East, but the details of their origins have been largely lost in the oral history. The Arabs came in several waves, beginning in the 14th century; their language has had a heavy influence on the indigenous languages of Chad because of its continued contact with them over the years. The Kanem-Borno empire, the Bagirmi kingdom, and the Wadai kingdom, which enjoyed ascendancy at different periods from the 9th to the 19th centuries, are in part responsible for the present-day use of Kanembu, Bagirmi, and Maba as vehicular languages. Finally, the French language arrived in Chad at the end of the nineteenth century as the colonizers' language of administration and education.

French, Arabic, and Other Languages of Wider Communication

Since Chad gained its independence in 1960, French has been the official language; Arabic was early proposed as a second official language, but this proposal has been a source of controversy. The Constitution of 1996 declared that French and Arabic are the official languages of Chad. But there has been some ambivalence as to whether the Arabic referred to is Modern Standard Arabic or vernacular Chadian Arabic. If Chad fit the pattern of diglossia common throughout the Arabic-speaking world, Standard Arabic would be deemed the only variety worthy of official status, the local vernacular (Chadian Arabic) being suitable only for oral informal communication. Nonetheless, Chadian Arabic is used in ways that would otherwise be considered inappropriate: it is used in formal settings (speeches, news broadcasts), and various efforts have been made to give it a standardized written form, even using Latin characters. A growing body of literature exists in Chadian Arabic. Further, the association of Arabic with Islam has made the Arabic question a bone of contention in Chad's officially secular society. It is true that Arabic does not enjoy widespread use in public life (e.g., in education, on signs and billboards, in newspapers) as compared with French, which is still seen as the language

Table 1 Chadian languages with more than 100 000 speakers[a]

Language (with classificatory affiliation)	*Number of native speakers (in thousands)*

(Adamawa family)	
Mundang	240
Tupuri	130

[a]Estimated numbers of native speakers in 2004, in thousands, based on projections of ethnic group population from the 1993 census (cf. Bureau Central du Recensement, 1994).

of prestige, the principal language of education and administration. The issue of a 'bilingual' Chad, where French and Arabic are used as equals on the national level, has engendered much debate (cf. Coudray, 1998).

In a country with about 130 languages, bilingualism is a necessity for interethnic communication, but the lingua franca used is not limited to the official languages. Some estimates reckon that only 30% of Chadians understand French, and only a very small minority of Chadians master Standard Arabic. On the other hand, those who understand vernacular Chadian Arabic may be as high as 70%. Chadian Arabic is widely used as a second language throughout the north and east of the country, and it is also gaining ground in certain areas of the south; 'Bongor Arabic' is the pejorative term used to describe the pidginized Arabic used in southwest Chad. But other Chadian languages are also used in specific geographic areas for interethnic communication: Fulfulde in the southwest near the Cameroon border; Sar in the far south, and/or a Sara-Ngambay mixture used across the south; Bagirmi along the Chari River; Kanembu in the area around Lake Chad; Dazaga in the north from Lake Chad across to the Sudan border; and Maba throughout much of eastern Chad.

In urban centers, such as the capital N'Djaména, speakers of diverse languages live side by side, and language use is adapted accordingly. It is common to hear frequent code switching between French, Chadian Arabic, and a local language, depending on the constraints of a given communication situation. Another urban phenomenon is 'common Sara,' forged by speakers of a diversity of Sara languages to enable them to communicate freely.

Use of Chadian Languages in Writing and Literacy

Only 33% of Chadians can read or write French or Arabic, according to a Census Bureau survey in 1998. But there are small numbers of literates in national languages, too. The government's Direction de l'Alphabétisation et de Promotion des Langues Nationales (DAPLAN) coordinates efforts in nonformal education, efforts to provide writing systems for Chadian languages, and efforts to develop pedagogical materials so that Chadian languages can be used in literacy programs.

A number of Chadian languages have been reduced to writing for specific practical purposes. Christian missionaries were the first to do so: translations of Bible portions first appeared in the Mbay language in 1932, in Mundang in 1933, and in Ngambay in 1936. This effort grew in subsequent years, so that today about 50 Chadian languages have some published religious materials, whether Bible portions, liturgical materials, or New Testaments and Bibles. In recent years, nonreligious development agencies and nongovernmental organizations have worked to disseminate health and agricultural materials in a variety of Chadian languages.

There are also grassroots efforts to further the use of Chadian languages. Numerous language committees and cultural associations have been formed in recent years with a view to promoting the local languages, developing local literacy programs on the village level, and developing a body of literature in these languages.

Classification and Linguistic Characteristics of Chadian Languages

The three phyla of African languages represented in Chad are Afro-Asiatic (Afrasian), Nilo-Saharan, and Niger-Congo.

Nilo-Saharan Languages

The Nilo-Saharan phylum is represented in Chad by the following branches (cf. Bender, 1996):

1. *Central Sudanic*, and specifically the Sara-Bagirmi group. More than one third of Chad's population speak languages from the Sara subgroup, which constitutes a dialect continuum in a broad band along the southern border with the Central African Republic. The principal Sara languages are Ngambay, Kaba, Gulay, Mbay, Sar, and Kaba Na, as well as a number of other, intermediate varieties, such as Gor, that have been dubbed dialects or languages according to different classifications. The Bagirmi subgroup, located further to the north, includes Bagirmi, Naba, and Kenga.
2. *Maban*, located in the Wadai near the Sudanese border: principal languages are Maba, Masalit, and Runga.
3. *Saharan* (located throughout the northern desert): its languages are Tedaga, Dazaga, Zaghawa (Beria), Kanembu, and Kanuri.
4. *Eastern Sudanic*, represented by the Tama group and Daju, spoken in eastern and central Chad.
5. *For*, represented by the Amdang language in the area of Biltine.

Linguistically, the Nilo-Saharan show the most diversity among Chadian languages. The Sara languages are quite simple morphologically and syntactically, while languages of the Saharan group show great complexity; the other subgroups show intermediate degrees of complexity.

Afro-Asiatic Languages: Chadic Family

More than one-third of Chadian languages belong to the Chadic family, one division of the Afro-Asiatic (or Afrasian) phylum. (Note that the adjective Chadic refers to this particular language family; the term Chadian refers to the country of Chad.) The following branches of the Chadic family are found in Chad (cf. Barreteau and Newman, 1978):

1. *East Chadic*. All the languages of this branch are spoken in Chad; it divides into two subgroups: the Guéra group (Newman's group "B"), located in the Guéra region of central Chad, whose major languages are Dangaléat, Migaama, Bidiyo, Mukulu, and Mubi; and the Chari-Logone group (Newman's group "A"), located between Chad's two major rivers, and whose major languages are Kera, Kwang, Nancere, Lele, Gabri, Somrai, and Tumak.
2. *Masa*. All languages of the Masa branch of Chadic are spoken in Chad, along its border with Cameroon. The main languages are Masana, Marba, Musey, and several varieties of Zime.
3. *Central Chadic (Biu-Mandara)*. Only a few languages of this branch are spoken in Chad, all located along the Cameroon border, notably Kotoko (several varieties), Buduma, Musgu, and Gidar.

These Chadic languages are normally characterized by grammatical gender in their nominal systems; their verbs may be marked for directionality and/or plurality of action. Vowels are often limited in number; some languages have even been analyzed as having only one underlying vowel, **a**. Many Chadic languages exploit labialization (lip-rounding) and palatalization (fronting) to a greater or lesserzz degree. Vowel length and consonant gemination are common phenomena in the languages of the Guéra subgroup.

Niger-Congo Languages: Adamawa Family

The Niger-Congo languages are represented in Chad essentially by the Adamawa family (cf. Boyd, 1989). Apart from a couple of isolate languages within Adamawa (Day, Laal), the languages spoken in Chad fall into two groups:

1. *Mbum group*, along the border with Cameroon; its principal languages are Mundang, Tupuri, and the Eastern Mbum cluster of Nzakambay, Kuo, and Karang. The languages of the Kim cluster, spoken along the Logone River, were originally recognized as a separate group but are now joined to the Mbum group.
2. *Bua group*, a cluster of languages spoken from the Chari River north to the Guéra; it includes Bua, Niellim, Tunia, Bolgo, and Gula varieties.

Adamawa languages are notable within the Niger-Congo phylum for their lack of a functioning noun class system; in general, the morphology and syntax of Adamawa languages are not greatly complex.

Common Features

A number of distinctive features of Chadian languages are worthy of mention because they can be found in languages of all three phyla. In the sound systems, many languages have phonemic implosives ɓ and ɗ (sometimes also ʃ); many have a series of prenasalized plosives (mb, nd, nj, ng); some have the retroflex flap ɽ; and the labial flap v̌ occurs with some regularity, especially in ideophones. A few languages have ATR vowel harmony (in certain Saharan, Maban, and Bua languages).

Most Chadian languages are tonal, although accent also seems to play an important role in some of them. Most languages have three register tones, which are relatively stable (i.e., not subject to spreading or downstep) but which can combine into tonal contours. Tone is exploited to make both lexical and grammatical distinctions.

SVO word order predominates in Chadian languages of all families; the only notable exception is the SOV order found in Saharan and Maban languages. Morphology is also relatively simple in most of the languages of southern Chad, regardless of classificatory affiliation. The Eastern Chadic languages have a somewhat richer morphology, but the greatest degree of morphological complexity is undoubtedly to be found in the verbal systems of the Saharan languages.

Prospects

Chadian languages have not received much attention from linguists. In the 1960s and 1970s, Europeans such as Jean-Pierre Caprile and Herrmann Jungraithmayr did active research (especially in the Sara languages and the Chadic languages, respectively). In recent years, Chadians have done research and description, especially through the National Institute of Human Sciences or the linguistics department of the University of N'Djaména. Other scholars and organizations, such as SIL, continue to engage in on-site linguistic research and description of Chadian languages.

But much remains to be done. The very existence of certain languages, such as Zerenkel or Mabire in the Guéra, has been discovered or confirmed only in

the past few years, because it is still difficult to reach many areas of Chad even today. And since so many of Chad's language groups are small, it is questionable how long the languages can continue. Indeed, several languages are already moribund, with only a handful of older speakers still living (e.g., Berakou, Mabire, Goundo), and a few others are seriously endangered because of language shift. Nonetheless, bilingualism of the mother tongue with another major language (such as Chadian Arabic) is stable among most groups; many remain relatively isolated from the mainstream; and in most groups children still learn the language of their parents. So most Chadian languages should remain to be spoken for at least two or three generations to come.

Introduction

The Chadic language family comprises an estimated 140 to 150 languages spoken in areas to the west, south, and east of Lake Chad (west Africa). The best-known and most widespread Chadic language is Hausa, with upwards of 30 million first-language speakers, more than any other language in Africa south of the Sahara. The remaining languages, some of which are rapidly dying out (often due to pressure from Hausa), probably number little more than several million speakers in total, varying in size from fewer than half a million to just a handful of speakers, and new languages continue to be reported. Written descriptions of varying length and quality are available for only about one-third of the total, although for some – e.g., Bidiya (Bidiyo), Guruntum, Kanakuru (Dera), Kera, Kwami, Lamang, Margi (Marghi Central), Miya, and Mupun – good descriptive grammars have been produced, and several dictionaries have appeared, e.g., Dangaléat, Lamé, Ngizim, and Tangale. Hausa has four recent comprehensive reference grammars, in addition to two

the past few years, because it is still difficult to reach many areas of Chad even today. And since so many of Chad's language groups are small, it is questionable how long the languages can continue. Indeed, several languages are already moribund, with only a handful of older speakers still living (e.g., Berakou, Mabire, Goundo), and a few others are seriously endangered because of language shift. Nonetheless, bilingualism of the mother tongue with another major language (such as Chadian Arabic) is stable among most groups; many remain relatively isolated from the mainstream; and in most groups children still learn the language of their parents. So most Chadian languages should remain to be spoken for at least two or three generations to come.

Chadic Languages

P J Jaggar, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The Chadic language family comprises an estimated 140 to 150 languages spoken in areas to the west, south, and east of Lake Chad (west Africa). The best-known and most widespread Chadic language is Hausa, with upwards of 30 million first-language speakers, more than any other language in Africa south of the Sahara. The remaining languages, some of which are rapidly dying out (often due to pressure from Hausa), probably number little more than several million speakers in total, varying in size from fewer than half a million to just a handful of speakers, and new languages continue to be reported. Written descriptions of varying length and quality are available for only about one-third of the total, although for some – e.g., Bidiya (Bidiyo), Guruntum, Kanakuru (Dera), Kera, Kwami, Lamang, Margi (Marghi Central), Miya, and Mupun – good descriptive grammars have been produced, and several dictionaries have appeared, e.g., Dangaléat, Lamé, Ngizim, and Tangale. Hausa has four recent comprehensive reference grammars, in addition to two

high-quality dictionaries, making it the best-documented language in sub-Saharan Africa.

Chadic is a constituent of the Afroasiatic phylum, which also includes Semitic (e.g., Amharic, Arabic, [Standard] Hebrew), Cushitic (e.g., Oromo, Somali), Omotic (e.g., Dime, Wolaytta), Berber (e.g., Tamahaq and Tamajeq [Tamajeq, Tayart] [spoken by the Tuareg], Tamazight [Central Atlas], and (extinct) Ancient Egyptian/Coptic. The phylogenetic membership of Chadic within Afroasiatic was first proposed almost 150 years ago, but did not receive wide acceptance until Greenberg's (1963) major (re)classification of African languages. The standard internal classification divides Chadic languages into three major branches: West (e.g., Hausa, Bole, Angas, Ron, Bade), Central = Biu-Mandara (e.g., Tera, Mandara, Bachama-Bata [Bacama], Kotoko [Afade]), and East (e.g., Somrai, Kera, Dangaléat), in addition to an isolated Masa cluster (with subbranches and smaller groupings).

Phonology

Laryngealized implosive stops, e.g., /b ɗ/, and ejective stops, e.g., /p' t'/, are widespread throughout Chadic, together with prenasalized obstruents, e.g., /mb nd/. A characteristic pattern, therefore, is for a language to present a four-way phonation contrast, e.g., coronal /t d ɗ nd/ and/or labial /p b ɓ mb/. The voiceless and voiced lateral fricatives /ɬ ɮ/ are also commonplace, in addition to palatal and velar (including labialized velar) consonants.

Vowel systems generally vary from two (monophthongal) vowels, high /ə/ (with various phonetic values) and low /a/, as in Bachama-Bata and Mandara, to seven vowels, e.g., [Dangaléat] /i e ɛ a ɔ o u/, with /i (e) a ə (o) u/ a common inventory, and the diphthongs /ai/ and /au/ are attested. Tangale has a nine-vowel ATR pattern. Contrastive vowel length, especially in medial position, is also widespread throughout the family.

Chadic languages are tonal, and two level (High/Low) tones, e.g., Hausa, or three (High/Mid/Low), e.g., Angas, are typical. Downstep is also common (e.g., Ga'anda, Miya, Tera). Although tone can be lexically contrastive, its primary function is normally grammatical, e.g., in distinguishing tense/aspect/mood categories. [Transcription: aa = long vowel, a = short; à(a) = L(ow) tone, â(a) = F(alling) tone, H(igh) tone is unmarked.]

Morphology and Syntax

Many Chadic languages have masculine/feminine grammatical gender (an inherited Afroasiatic feature), with no distinction in the plural, and typically distinguish gender in second and third person singular pronouns, e.g., [Miya] fiy/macə 'you (MASC/FEM)', tə/njə 'he/she'. Some also preserve the characteristic n/t/n (MASC/FEM/PL) marking pattern in grammatical formatives (and the masculine and plural markers often fall together phonologically), cf., [Masa] vèt-*n*a 'rabbit', vèt-*t*a 'female rabbit', vèdai-*n*a 'rabbits'.

Noun pluralization is complex, and some widespread plural suffixes are reconstructable for Proto-Chadic, e.g., *-Vn, *-aki, *-i, and *-ai. Examples: (-Vn) kùmən/kùmən*ən* 'mouse/mice' [Bade], miyò/mish*an* 'co-wife/co-wives' [Kanakuru], (-aki) goonaa/gòon*àkii* 'farm(s)' [Hausa], (-i) duwimà/dùwìm*i* 'guineafowl(s)' [Gera], (-ai) mùtù/mu*ta*i 'sore(s)' [Dangaléat]. Other plurals entail infixation of internal -a-, e.g., [Ron] sàkur/sakw*âa*r 'leg(s)'. Some languages restrict overt plural marking to a narrow range of nouns (typically humans and animals).

Verbs in many Chadic languages have retained the lexically arbitrary Proto-Chadic distinction between final –a and final –ə verbs (where the final schwa vowel is often pronounced as [i], [ə], or [u]), cf., [Tera] na 'see' and dlə 'get', [Guruntum] daa 'sit' and shi 'eat'. Verbal semantics and valency are modified by the addition of one or more derivational extensions (often fused suffixes). These extensions encode such notions as action in the direction of (centripetal) or away from (centrifugal) a deictic center (often the speaker), or action partially or totally completed, e.g., (totality) sà-nyà 'drink up' < sà 'drink' [Margi]. Some extensions also have a syntactic function, denoting, *inter alia*, transitivization or perfectivity, e.g., (transitivization) yàw-tu 'take down' < yàwwu 'go down' [Bole], kàta-naa 'return' (TRANS) < kàtee 'return' (INTRANS) [Ngizim]. Verb stems can be overtly inflected for tense-aspect-mood by segmental and/or tone changes.

Many languages also have so-called 'pluractional' verbs, which express an action repeated many times or affecting a plurality of subjects (if intransitive) or objects (if transitive), and are formed via prefixal reduplication, ablaut or gemination, e.g., [Guruntum] pàni/*pàp*pàni 'take', [Angas] fwin/fw*a*n 'untie', [Pero] lofò/lo*ff*ò 'beat'. In some languages, pluractional stems occur with plural subjects of intransitive verbs and plural objects of transitive verbs, producing ergative-type agreement. In a number of languages, intransitive verbs are followed by an 'intransitive copy pronoun', which maps the person, number, and gender of the coreferential subject, e.g., [Kanakuru] nà pòrò-*no* 'I went out' (literally I went out-*I*).

Derivational and inflectional reduplication is widespread throughout the family (often signaling semantic intensification), ranging from (a) copying of a single segment, e.g., [Miya] pluractional verb tly*aa*ɗə

'to hoe repeatedly' < tly*ad*ə 'to hoe', [Bidiya] tà*tt*uk 'very large' < tà*t*uk 'large'; (b) reduplication of a syllable, e.g., [Hausa] prefixal reduplication of the initial CVC syllable of a sensory noun to form an intensive sensory adjective, as in *zùz*zurfaa 'very deep' (< *zur*-zurf-aa) < *zur*fii 'depth' (with gemination/assimilation of the coda /r/); (c) full reduplication (exact copy), e.g., [Guruntum] kìnì-kìnì 'just like this' < kìnì 'like this', [Kwami] kayò-kayò 'a gallop' < kayò 'a ride', [Tangale] sàŋ-sàŋ 'very bright' < sàŋ 'bright', [Margi] pərda-pərda 'sinewy piece of meat' < pərda 'sinew'.

Like many African languages, Chadic languages often have a lexically autonomous class of highly expressive, phonosemantic words known as 'ideophones'. Ideophones usually pattern syntactically with adverbials and often have their own distinct phonological and phonotactic properties. They typically reinforce the manner of an action, event, or state, e.g., [Ngizim] ɓərak 'with a popping sound', [Miya] ɓakù-ɓakù 'hopping along', [Kwami] (adjectival) dùkùɗù 'small and broad', [Hausa] kwàngàr̃àm 'with a clang', [Margi] dzùl-dzùl 'jumping high in running (animal)', [Bidiya] ɓorok (Mid tones) 'emphasizes quickness'.

Word order is normally S[ubject] V[erb] O[bject], although VSO order is found in a few Central Chadic/Biu-Mandara languages spoken in the Nigeria–Cameroon border area. Pronominal indirect objects (recipients/goals) are typically realized as verb clitics, whereas nominal indirect objects occur as prepositional phrases to the right of the direct object/theme (Chadic languages are prepositional), cf., [Kanakuru] à jòɓ-*rò* landài 'he washed the robe for her' (literally he washed-*for her* robe), and à jòɓè landài *gən tamno* 'he washed the robe for the woman' (literally he washed robe *for woman*). *Wh*-questions, focus, and relativization usually pattern together in terms of their formal morphosyntactic reflexes, with overt movement, often to left periphery, and special (focus) marking on the infl(ectional) element, e.g., [Hausa] yaaònkà mukà ganii 'it's your boy (that) we saw' (literally boy.your 1pl.FOCUS.PERF see). Some languages allow (or require) in situ *wh*- and (pragmatic) focus constituents, e.g., [Duwai] Saaku bə̀nə *mù*? 'what did Saku cook?' (literally Saku cooked *what*).

Negation in Chadic is typically signaled with a single marker in sentence-final position, e.g., [Guruntum] tâa kyur shau *dà* 'she will not cook the food' (literally she will cook food NEG), [Kera] wə gùsnə̀ hàrga *bà* 'he didn't buy her a goat' (literally he bought her goat NEG), sometimes reinforced by an additional pre-verbal negative marker. Comparatives are normally ditransitive constructions with the lexical verb 'exceed, surpass, be more than', i.e., exceed object X in relation to manner Y.

In noun phrase syntax, the normative order for constituents is head-initial, i.e., head noun followed by definite determiners, possessives, numerals, relative clauses, etc. The linear order in genitive constructions is possessee X (+ 'of' linker) + possessor Y, e.g., [Margi] tagu gə Haman 'Haman's horse' (literally horse of Haman). Many Chadic languages also make an overt distinction between alienable and inalienable possession whereby inalienable possession is expressed by direct juxtaposition (i.e., with no overt linker), cf. (inalienable) mənda Miyim 'Miyim's wife' (literally wife Miyim), and (alienable) gam ma tamnoi 'the woman's ram' (literally ram of woman) [Kanakuru]. Reflexive pronouns and reciprocals (phrasal anaphors) are typically formed with the body-part nouns 'head' and 'body' respectively, e.g., [Kwami] kuu-nì 'himself' (literally head-his), [Miya] tuwatùw-àamà 'each other (we)' (literally body-our).

Chamberlain, Basil Hall (1850–1935)

M McCaskey, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Basil Hall Chamberlain (1850–1935) was born in Southampton, England, but educated in France and Switzerland. His family wanted him to become a banker in London, but he went to Japan instead, on the grounds that travel would be better for his health. He arrived in Japan in 1873 to begin intensive study of the Japanese language. In 1876, he became a lecturer in English language and literature at Tokyo University. Having independent means, however, he decided to resume his own studies a year later. He resumed teaching English, at the Japanese Naval Academy from 1874 to 1882, since this post paid well and allowed him time for his own language studies as well.

In 1886, he became professor of Japanese and philology at Tokyo Imperial University, specializing in historical linguistics. He was among the first Westerners to do serious advanced research on Japanese academic subjects, and one of his advanced students at Tokyo University, Ueda Kazutoshi (1867–1937), became a pioneer in developing modern Japanese lexicography and the study of linguistics in Japan.

In addition to his work on standard Japanese, Chamberlain studied the Japanese language variants used in the Ryukyu Islands, as well as the Ainu language, then still spoken widely in northern Hokkaido. He began studying Korean in 1881 and subsequently did comparative linguistic studies of Japanese, Ryukyu dialect, Ainu, and Korean, initiating research carried on and developed by Hattori Shirō and other Japanese linguists two generations later.

In 1880, Chamberlain began his research on the *Kojiki,* the oldest Japanese history text written in the Japanese language. In 1883 he published a translation, the *Ko-ji-ki or records of ancient matters* (Chamberlain, 1982), with notes by William George Aston (1841–1911), the Tokyo British embassy secretary. Aston was a Japanese language specialist who published a companion translation of the *Nihon shoki* (1896), the oldest Japanese history text written in classical Chinese. Chamberlain continued his *Kojiki* research after leaving Japan, publishing his final version in 1932. The next full English *Kojiki* translation did not appear until 1969.

Though Chamberlain's professional focus was on classical literature and linguistic analysis, he also wrote a series of popular books introducing Westerners to Japanese language and culture. *A handbook of colloquial Japanese* (1888) designed for use by learners at a basic level, was widely used for more than half a century, until it was superseded by more complete references in English after World War II. Chamberlain's *Things Japanese* (1890), one of the few books available in this area then, was a popular introduction to Japanese social life and customs and is still in print today.

Chamberlain, Basil Hall (1850–1935)

M McCaskey, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Basil Hall Chamberlain (1850–1935) was born in Southampton, England, but educated in France and Switzerland. His family wanted him to become a banker in London, but he went to Japan instead, on the grounds that travel would be better for his health. He arrived in Japan in 1873 to begin intensive study of the Japanese language. In 1876, he became a lecturer in English language and literature at Tokyo University. Having independent means, however, he decided to resume his own studies a year later. He resumed teaching English, at the Japanese Naval Academy from 1874 to 1882, since this post paid well and allowed him time for his own language studies as well.

In 1886, he became professor of Japanese and philology at Tokyo Imperial University, specializing in historical linguistics. He was among the first Westerners to do serious advanced research on Japanese academic subjects, and one of his advanced students at Tokyo University, Ueda Kazutoshi (1867–1937), became a pioneer in developing modern Japanese lexicography and the study of linguistics in Japan.

In addition to his work on standard Japanese, Chamberlain studied the Japanese language variants used in the Ryukyu Islands, as well as the Ainu language, then still spoken widely in northern Hokkaido. He began studying Korean in 1881 and subsequently did comparative linguistic studies of Japanese, Ryukyu dialect, Ainu, and Korean, initiating research carried on and developed by Hattori Shirō and other Japanese linguists two generations later.

In 1880, Chamberlain began his research on the *Kojiki,* the oldest Japanese history text written in the Japanese language. In 1883 he published a translation, the *Ko-ji-ki or records of ancient matters* (Chamberlain, 1982), with notes by William George Aston (1841–1911), the Tokyo British embassy secretary. Aston was a Japanese language specialist who published a companion translation of the *Nihon shoki* (1896), the oldest Japanese history text written in classical Chinese. Chamberlain continued his *Kojiki* research after leaving Japan, publishing his final version in 1932. The next full English *Kojiki* translation did not appear until 1969.

Though Chamberlain's professional focus was on classical literature and linguistic analysis, he also wrote a series of popular books introducing Westerners to Japanese language and culture. *A handbook of colloquial Japanese* (1888) designed for use by learners at a basic level, was widely used for more than half a century, until it was superseded by more complete references in English after World War II. Chamberlain's *Things Japanese* (1890), one of the few books available in this area then, was a popular introduction to Japanese social life and customs and is still in print today.

He returned to Europe permanently in 1911, after almost 40 years in Japan, and spent the remaining two dozen years of his life in Switzerland. He continued to research and write about Japan and revise his earlier works for definitive publication. He spent time visiting his younger brother, the controversial author Houston Stewart Chamberlain (1855–1927), a prominent ultranationalist and activist in Germany who later became a German citizen. Unlike Houston, Basil spent his life immersed in studying the culture of another country without losing a scholarly perspective. The fact that Basil's complete works were republished in 2000 (Chamberlain, 2000) testifies to the value of his contributions to the study of Japanese language and culture.

Champollion, Jean-François (1790–1832)

F S O'Rourke, Somerset County Library System, Princess Anne, MD, USA

S C O'Rourke, Yale University, New Haven, CT, USA

© 2006 Elsevier Ltd. All rights reserved.

Jean-François Champollion, born December 23, 1790, was an Orientalist most remembered for his decipherment of ancient Egyptian hieroglyphics such as those found on the storied Rosetta Stone. Others, including English physicist Thomas Young, had labored for many years to reveal what the hieroglyphics symbolized, but it was Champollion – with knowledge of these foregoing efforts, his expertise in many languages, and his research on the cartouches of the pharaohs – who was the first to successfully unravel the mystery, beginning late in 1821 and into 1822. Champollion's breakthrough furthered Young's own suspicions that some hieroglyphics had phonetic values. His discoveries enabled scholars to accurately translate hieroglyphic texts and were therefore crucial to the current understanding of ancient Egyptian civilization.

The Rosetta Stone, a dark granite stela bearing the same text in three different scripts (Egyptian demotic, Egyptian hieroglyphic, and Greek – the first two representing a single language), was unearthed in 1799 at a construction site near the town of el-Rashid, or Rosetta, in the Nile River delta during Napoleon Bonaparte's ill-fated campaign in Egypt. It fell to the English after the French were defeated in Egypt and has been on exhibit at the British Museum in London almost continuously since 1802.

Born in Figeac, France, during the unrest of the French Revolution, Champollion received virtually no formal schooling at as early age, although he taught himself to read and became well-versed in Greek and Latin. In 1801 he was sent to Grenoble to live with his older brother, Jacques-Joseph Champollion-Figeac, a great source of inspiration for Champollion and a noted archaeologist and paleographer; Champollion became known as *le jeune*.

Champollion's propensity for languages flourished under the influence of his brother and Joseph Fourier, a mathematician, physicist, and prominent member of Napoleon's mission in Egypt who first met Champollion in 1802 while holding office in Grenoble. Champollion eventually studied Arabic, Avestan, Chinese, Coptic, Hebrew, Pahlavi, Persian, Sanskrit, and Syriac, among other languages. In 1807, at the age of 16, he addressed the Société des Sciences et des Arts de Grenoble (later the Académie delphinale) and soon afterwards, became its youngest member. He continued to follow his conviction that the more modern Coptic language would play an important role in the decipherment of the ancient Egyptian inscriptions. In 1809, after studying in Paris for several years under such figures as Silvestre de Sacy, Champollion was appointed to an academic post in history in Grenoble. In the following year he was named docteur ès lettres. He later fell victim to the political hostilities at the onset of the Bourbon Restoration and lost his position at Grenoble in 1816, although was given a chair in history and geography there in 1818.

He returned to Europe permanently in 1911, after almost 40 years in Japan, and spent the remaining two dozen years of his life in Switzerland. He continued to research and write about Japan and revise his earlier works for definitive publication. He spent time visiting his younger brother, the controversial author Houston Stewart Chamberlain (1855–1927), a prominent ultranationalist and activist in Germany who later became a German citizen. Unlike Houston, Basil spent his life immersed in studying the culture of another country without losing a scholarly perspective. Jean-François Champollion, born December 23, 1790, was an Orientalist most remembered for his decipherment of ancient Egyptian hieroglyphics such as those found on the storied Rosetta Stone. Others, including English physicist Thomas Young, had labored for many years to reveal what the hieroglyphics symbolized, but it was Champollion – with knowledge of these foregoing efforts, his expertise in many languages, and his research on the cartouches of the pharaohs – who was the first to successfully unravel the mystery, beginning late in 1821 and into 1822. Champollion's breakthrough furthered Young's own suspicions that some hieroglyphics had phonetic values. His discoveries enabled scholars to accurately translate hieroglyphic texts and were therefore crucial to the current understanding of ancient Egyptian civilization.

The Rosetta Stone, a dark granite stela bearing the same text in three different scripts (Egyptian demotic, Egyptian hieroglyphic, and Greek – the first two representing a single language), was unearthed in 1799 at a construction site near the town of el-Rashid, or Rosetta, in the Nile River delta during Napoleon Bonaparte's ill-fated campaign in Egypt. It fell to the English after the French were defeated in Egypt and has been on exhibit at the British Museum in London almost continuously since 1802.

Born in Figeac, France, during the unrest of the French Revolution, Champollion received virtually no formal schooling at as early age, although he taught himself to read and became well-versed in Greek and Latin. In 1801 he was sent to Grenoble to live with his older brother, Jacques-Joseph Champollion-Figeac, a great source of inspiration for Champollion and a noted archaeologist and paleographer; Champollion became known as *le jeune*.

Champollion's propensity for languages flourished under the influence of his brother and Joseph Fourier, a mathematician, physicist, and prominent member of Napoleon's mission in Egypt who first met Champollion in 1802 while holding office in Grenoble. Champollion eventually studied Arabic, Avestan, Chinese, Coptic, Hebrew, Pahlavi, Persian, Sanskrit, and Syriac, among other languages. In 1807, at the age of 16, he addressed the Société des Sciences et des Arts de Grenoble (later the Académie delphinale) and soon afterwards, became its youngest member. He continued to follow his conviction that the more modern Coptic language would play an important role in the decipherment of the ancient Egyptian inscriptions. In 1809, after studying in Paris for several years under such figures as Silvestre de Sacy, Champollion was appointed to an academic post in history in Grenoble. In the following year he was named docteur ès lettres. He later fell victim to the political hostilities at the onset of the Bourbon Restoration and lost his position at Grenoble in 1816, although was given a chair in history and geography there in 1818.

In 1822 Champollion stunned the academic world with his celebrated *Lettre à M. Dacier*, in which he announced his success in identifying the values of a number of hieroglyphics from Egyptian texts. His achievements came to the attention of the French kings Louis XVIII and Charles X and Champollion first reaped the rewards of royal favor when he was sent on a tour of Italian museums to study their collections of Egyptian antiquities. He was also honored in 1826 with an appointment as curator of the soon-to-open Egyptian and Oriental collections at the Louvre in Paris. Champollion continually refined his analysis of the hieroglyphic system over the years and by the end of his short life he had concluded that it consisted of three types of elements: those with phonetic values (be they syllabic or purely alphabetic), ideograms (figurative or symbolic in nature), and determinatives (providing information as to semantic sense and pronunciation). Others before him had failed to realize that the system was complex as such. Champollion's work on the hieroglyphic system also clarified the relation between it and two descendent scripts of ancient Egypt, demotic and hieratic.

Champollion mounted a joint expedition to Egypt in 1828 with his Italian colleague Ippolito Rosellini, during which Champollion conducted the first systematic survey of the monuments and hieroglyphic inscriptions found there. Although criticized by some for removing such inscriptions, many of which would later appear in museums abroad, others feel that in doing so, Champollion and others may have saved them from destruction. In 1830 he was elected to the Académie des Inscriptions et Belles-Lettres; the following year the Collège Royal (later Collège de France) in Paris established a chair in archaeology for him. He died after a series of strokes on March 4, 1832 at the age of 41. Many of his manuscripts, including his Egyptian dictionary and grammar, were published posthumously by his brother and others.

Champollion is widely considered the father of the modern discipline of Egyptology. For his sheer brilliance, professional accomplishments, and devotion to all aspects of the field, Champollion was often referred to as *the Egyptian*.

Channel Islands: Language Situation

M C Jones, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

The Channel Islands (see **Figure 1**) constitute a small archipelago off the west coast of the Cotentin peninsula of Normandy. The eight islands, in descending order of size, are Jersey, Guernsey, Alderney, Sark, Herm, Jethou, Lihou, and Brecqhou. The precise date of the Roman occupation of the islands and hence of the introduction of Latin is unknown but it can be assumed that Latin and, later, some form of Romance speech have been spoken there for approximately two millennia. Despite the fact that the archipelago was separated from the Duchy of Normandy in 1204 and has, from that time on, formed part of the British Isles (although the islands are self-governing: Jersey forms its own bailiwick and the other islands form the bailiwick of Guernsey), until relatively recently the majority of the inhabitants spoke Norman French dialects closely related to those of the neighboring mainland.

Figure 1 The Channel Islands.

English was introduced to the islands in the Middle Ages, when garrisons were established there, but the local dialects remained as the everyday variety of the majority of the Islanders until well into the nineteenth century, when the growth of trade and tourism led to progressive Anglicization. The evacuation of many of the inhabitants to the British mainland in the days preceding the German occupation of the islands during the Second World War had severe linguistic repercussions. Alderney, where the local dialect (Auregnais) was already moribund, was totally evacuated and the dialect is now extinct. Since the standard language of all the Channel Islands has been French and never the indigenous dialects, their presence in 'official' domains has been virtually nonexistent. Standard French (and now English) has been the language of religion and legislation and English has always been dominant in the education system. Today, Standard French is reserved largely for ceremonial functions.

Official statistics for speakers of the local dialects have been gathered twice for Jersey (in the 1989 and 2001 censuses) and once for Guernsey (in the 2001 census). A comparison of the Jersey results from the two censuses provides us with a clear indication of the decline of the dialect in recent years. In 1989, there were 5720 speakers of Jersey French (Jèrriais), representing 6.9% of the total resident population. By 2001, this had gone down to 2874 speakers, or 3.2% of the total resident population, with some two-thirds of these speakers aged over 60. The 2001 census also recorded that only 113 speakers declared Jèrriais to be their usual everyday language. On Guernsey, the number of people able to speak Guernsey French (Guernesiais) fluently in 2001 was 1327, or 2.2% of the total resident population, with nearly 70% of these speakers aged over 64. No such information has been gathered for Sark, although it is estimated that fewer than 20 out of the 600 permanent inhabitants can speak Sark French (Sercquiais).

Despite their linguistic affinity with mainland Norman, the dialects of the Channel Islands show salient differences from the mainland varieties – and from

The Channel Islands (see Figure 1) constitute a small archipelago off the west coast of the Cotentin peninsula of Normandy. The eight islands, in descending order of size, are Jersey, Guernsey, Alderney, Sark, Herm, Jethou, Lihou, and Brecqhou. The precise date of the Roman occupation of the islands and hence of the introduction of Latin is unknown but it can be assumed that Latin and, later, some form of Romance speech have been spoken there for approximately two millennia. Despite the fact that the archipelago was separated from the Duchy of Normandy in 1204 and has, from that time on, formed part of the British Isles (although the islands are self-governing: Jersey forms its own bailiwick and the other islands form the bailiwick of Guernsey), until relatively recently the majority of the inhabitants spoke Norman French dialects closely related to those of the neighboring mainland.

Figure 1 The Channel Islands.

English was introduced to the islands in the Middle Ages, when garrisons were established there, but the local dialects remained as the everyday variety of the majority of the Islanders until well into the nineteenth century, when the growth of trade and tourism led to progressive Anglicization. The evacuation of many of the inhabitants to the British mainland in the days preceding the German occupation of the islands during the Second World War had severe linguistic repercussions. Alderney, where the local dialect (Auregnais) was already moribund, was totally evacuated and the dialect is now extinct. Since the standard language of all the Channel Islands has been French and never the indigenous dialects, their presence in 'official' domains has been virtually nonexistent. Standard French (and now English) has been the language of religion and legislation and English has always been dominant in the education system. Today, Standard French is reserved largely for ceremonial functions.

Official statistics for speakers of the local dialects have been gathered twice for Jersey (in the 1989 and 2001 censuses) and once for Guernsey (in the 2001 census). A comparison of the Jersey results from the two censuses provides us with a clear indication of the decline of the dialect in recent years. In 1989, there were 5720 speakers of Jersey French (Jèrriais), representing 6.9% of the total resident population. By 2001, this had gone down to 2874 speakers, or 3.2% of the total resident population, with some two-thirds of these speakers aged over 60. The 2001 census also recorded that only 113 speakers declared Jèrriais to be their usual everyday language. On Guernsey, the number of people able to speak Guernsey French (Guernesiais) fluently in 2001 was 1327, or 2.2% of the total resident population, with nearly 70% of these speakers aged over 64. No such information has been gathered for Sark, although it is estimated that fewer than 20 out of the 600 permanent inhabitants can speak Sark French (Sercquiais).

Despite their linguistic affinity with mainland Norman, the dialects of the Channel Islands show salient differences from the mainland varieties – and from

each other. The dialects spoken in Jersey and Guernsey also display considerable regional variation.

An embryonic language support campaign currently exists on Jersey (where the dialect has recently been standardized), including limited teaching of Jèrriais in school (from September 1999). Since January 2004, Guernesiais has been taught to children of infant school age in three of Guernsey's primary schools. There is nothing comparable in Sark.

The dialects have left a substrate imprint on the distinctive variety of English spoken in the Channel Islands. However, with increasing immigration from the UK, this variety is not as widespread as it once was.

A limited amount of literary output has been produced in the local dialects of Jersey and Guernsey.

Chao Yuen Ren (1892–1982)

R J LaPolla, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

Y. R. Chao is easily the most famous linguist to have come out of China. Born before the end of the last dynasty in China, he received a traditional Confucian education, but was also one of the first Chinese people to be sent to the West for training in modern Western science (under the Boxer Indemnity Fund). The remarkable breadth and scope of his studies included physics, mathematics, linguistics, musical and literary composition, and translation, and he was a pioneer in many of these fields. Chao received a B.A. in mathematics from Cornell University in 1914, and a Ph.D. in philosophy from Harvard in 1918, but began his career teaching physics at Cornell and Harvard. He returned to China in 1920 to take a position at Tsing Hua University; there he acted as interpreter for Bertrand Russell, Dora Black, and John Dewey. He was involved in the vernacular literature movement, in 1922 translating *Alice in Wonderland* into vernacular Chinese, and also in the national language and standardization movement. He developed the system of National Romanization that was adopted by the government and was one of the key members of the group that created the national language, with his voice being the one on the recordings of the new national and standard language. In the late 1920s, when the Academia Sinica was founded, he became the head of the linguistics section of the Institute of History and Philology. There he organized teams to go to the field to systematically record the different Chinese dialects, and published his *Studies of the modern Wu dialects,* the earliest descriptive work of its kind in China. It was also in those years that he wrote his famous article 'On the non-uniqueness of phonemic solutions of phonetic systems.' During the war years he was back in the U.S., in Hawaii, then Yale and Harvard. He was recruited to lead the U.S. Army Chinese language program at Harvard, where he wrote his *Cantonese primer* (1947) and *Concise dictionary of spoken Chinese* (1946). These publications also led to his *Mandarin primer* (1961), *Readings in sayable Chinese* (1968), and *Grammar of spoken Chinese* (1968), still the best grammar of Mandarin Chinese available. It is an amazing piece of scholarship not only for its incredible thoroughness, but also because of his insightful inductive analysis, taking Chinese on its own terms (in fine structuralist tradition) rather than trying to force it into any preconceived categories.

In 1947 he was on his way back to China, but stopped off at the University of California at Berkeley, where he was offered a position, in which he remained until he retired in 1960, becoming Agassiz Professor of Oriental Languages and Literatures in 1952. His contributions were also recognized by his election to president of the Linguistic Society of America in 1945 and president of the American Oriental Society in 1960. Among his well-known students are Wang Li (*see* **Wang Li (1900–1986)**), Kun Chang (who replaced Chao at Berkeley upon his retirement), and Jerry Norman.

Character Sets

J H Jenkins, Apple Computer, Inc., Cupertino, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Everything is a number to a computer, and so, in order to represent text, it is necessary to create a numerical representation for it. The most common technique for doing so is to assign numbers to individual characters in a writing system; the term 'character set' is used to refer to such a mapping.

More specifically, everything is a binary number of a fixed size to a computer. A single binary digit is referred to as a bit. Because the binary representation of a number is difficult for humans to use, computer scientists usually use base 8 (octal) or base 16 (hexadecimal) numbers. In octal numerals, only the digits 0 through 7 are required; hexadecimal uses 0 through 9 and A through F as digits. When it is unclear which base is being used, octal numerals are written with a leading 0, and hexadecimal numerals with a leading 0x.

The smallest-size number a computer can readily manipulate is called a byte. Earlier systems used bytes that varied in size from computer to computer; today, an eight-bit byte or octet is standard. Bytes are the basis of data interchange between different computers.

We can therefore say that a character set is a mapping between a set of text elements such as characters to a series of bytes. Conceptually, this process can be broken down into stages (see Figure 1):

1. the abstract character repertoire, which is the collection of characters to be encoded;
2. the coded character set, which maps the elements of an abstract character repertoire to a set of non-negative integers;
3. the character encoding form, which maps the elements of a coded character set to code units of a specific size; and
4. the character encoding scheme, which maps code units from one or more character encoding forms to an actual sequence of bytes.

History

The first efforts to create numerical encodings for text date from the 19th century with the advent of telegraphy. As the technology advanced and developed, so did increasingly sophisticated techniques to coordinate the transmission of textual information via numerical or other codes and the technology used for transmission. This dovetailed with the pioneering work in computers to create the first computer character sets.

The most direct descendant of the telegraphy codes is EBCDIC (Extended Binary Coded Decimal Interchange Code), used in IBM mainframe computers from the early 1960s onwards. Its chief rival was the American Code for Standard Information Interchange (ASCII), developed at about the same time by what is now the American National Standards Institute (ANSI). ASCII has proven far more popular and influential; use of EBCDIC has been restricted largely to IBM mainframes and closely related systems.

ASCII represents characters using units of seven bits, which provides for a set of $2^7 = 128$ characters. The first 32 and last one are used for control codes – numbers that do not represent text but are used to give instructions to the machines displaying or printing it. (Character 0x08, for example, was frequently used to instruct a terminal to ring its bell.) The remaining 95 are the characters for display. In its current form, ASCII includes the upper- and lower-case letters of the Latin alphabet as used for English, the numerals 0 through 9, basic punctuation, and some accents. The accents were used for non-English languages. A French 'é' would be represented by instructing the terminal to type 'e', physically move backwards one place, and then type the accent.

ASCII is sufficient for use with standard modern English as typed on typewriters, but not for anything else. Nor is it actually sufficient even for English typesetting, as it is missing important symbols such as em and en dashes.

On systems based on the eight-bit byte, the use of ASCII seems wasteful, since that eighth bit is unused. Originally it was intended that the extra bit should be used as a parity bit as a redundancy check. By the 1980s, however, eight-bit extensions to ASCII had become common. The first 128 characters, 0x00 through 0x0F, were as in ASCII, and the remaining 128 were used for extensions such as dingbats or additional letters. Most notable of the eight-bit character sets are MacRoman, developed by Apple Computer for use on its Macintosh computers, and the ISO 8859 series of standards developed by the International Organization for Standardization.

Eight-bit character sets are inadequate for languages requiring more than 256 characters. Extensions were developed, therefore, for use in East Asia. The most common are referred to as double-byte character sets. In these character sets, the bytes 0x00 through 0x7F are used as ASCII. Bytes 0x80 through 0xFF are available to signal the start of

Abstract character repertoire:	A, B, C, D,…
Coded character set:	A → 65, B → 66, C → 67, D → 66,…
Character encoding form:	A → 0x0041, B → 0x0042, C → 0x0043, D → 0x0044,…
Character encoding scheme:	ABCD → 00 41 00 42 00 43 00 44, or ABCD → 41 00 42 00 43 00 44 00

Figure 1 Stages in the character-encoding process.

two-byte units. The Latin letter 'A' would therefore be represented by the single byte 0x41, and the Chinese character 井 by the two-byte sequence 0xA4AB. Such techniques provide enough room for the daily needs of modern East Asian languages.

By 1990, there were dozens of character sets in common use, with varying repertoires and architectures. This created problems for software companies, whose products were originally written with ASCII or one of its eight-bit extensions in mind. Getting software to work with multiple character sets was a long and expensive process. This led to the desire for a universal character set, adequate for the representation of all languages.

Two efforts to produce a universal character set converged in the early 1990s. One is known as ISO/IEC 10646, produced by the international standardization community. The other is Unicode, produced by the Unicode Consortium, an industry consortium consisting largely (but not entirely) of companies headquartered in the United States. The convergence of the two character sets means that the terms 'Unicode' and 'ISO/IEC 10646' can be used almost interchangeably in most circumstances. We will generally use the term 'Unicode', as Unicode is formally an implementation of ISO/IEC 10646 with additional specifications.

The existence of a universal character set has proven vital in the rise of the Internet. So long as documents are created and printed on a single computer, it doesn't make much difference which character set is used. When a user in Nome, Alaska is using his Windows system to access a Japanese Web page hosted by a computer in Calcutta running Linux, however, it becomes important to make sure that both systems can handle the same character set. And when that computer in Calcutta is used to host the records of a multinational corporation requiring support for English, French, Chinese, Japanese, Hindi, and Thai, it becomes even more important to avoid the accounting headache of dealing with multiple character sets.

By the turn of the 21st century, Unicode and ISO/IEC 10646 had become the focus of all efforts to extend the computer representation of human languages. They are also increasingly supported by modern operating systems and software.

Characteristics of Unicode

Unicode was originally based on a simple 16-bit architecture: there were $2^{16} = 65\,536$ code points available from 0x0000 through 0xFFFF. The first 128 code points are identical with ASCII; indeed, the first 256 code points are identical with the popular eight-bit standard, ISO 8859-1. The remaining space included characters of well over a dozen other scripts ranging from Greek to Thai. Numerals and punctuation marks were included, together with mathematical symbols and popular dingbats.

It soon became clear that this was insufficient room for the full set of characters people actually wanted to use. Sixteen additional planes each of 65 536 code points each were added and multiple encoding forms created, as described below, to accommodate them.

The number assigned a character is referred to as its Unicode scalar value (USV), and is usually written as 'U+' followed by four or more hexadecimal digits. Each character is also assigned a name. The Latin letter 'A' has U+0041 for its USV and is named LATIN CAPITAL LETTER A. In addition to standalone characters, Unicode includes a number of combining marks. These are included to allow support for on-the-fly generation of new accented forms. This makes it unnecessary to actually catalogue every accented Latin letter, for example, before it can be represent on computers.

Several thousand code points are reserved for private use; that is, the standard does not define what they are to represent but leaves that to private agreements between different users. This allows users to interchange data using unencoded characters or characters inappropriate for encoding, such as corporate logos.

One of the most controversial aspects of Unicode is its inclusion of a unified set of ideographs for all of East Asia: Chinese (both its simplified and traditional forms), Japanese, and Korean. (Unicode and ISO/IEC 10646 use the linguistically incorrect term 'ideograph' for historical reasons. The authors of both standards are aware that other terms better describe the function of these characters in the languages that use them.) The process of producing a single set of characters for East Asian languages is referred to as

Character	Chinese (PRC)	Chinese (Taiwan)	Japanese	Korean
U+4E95	井	井	井	井
U+753B	画	画	画	
U+76F4	直	直	直	直
U+8435	葛	葛	葛	葛

Figure 2 Han unification.

Han unification (see Figure 2). Because individual characters are often written in visually distinct ways in different parts of East Asia, there was some concern that this would force, for example, a Japanese user to see their name written with culturally inappropriate Chinese glyphs; and because the Unicode Consortium itself and the bulk of its officers are American, it was also felt that Americans were being insensitive to the needs of people in East Asia.

Both fears proved to be overstated. In point of fact, most Japanese users use systems with fonts designed specifically for Japanese and only rarely are confronted by Japanese text written using Chinese glyphs. Even where they are, the glyphs they see would generally be perfectly acceptable, or, at most, about as odd-looking as the spelling 'colour' is to an American or 'color' to a Briton. The actual work of Han unification, moreover, has been done by an international group. This group, now called the Ideographic Rapporteur Group or IRG, currently has delegations representing the People's Republic of China (PRC), the Special Administrative Regions of Hong Kong and Macao, Taiwan, North and South Korea, Japan, Vietnam, Singapore, and the United States, with a liaison representing the Unicode Consortium. The current head of the IRG is Dr Lu Qin of Hong Kong Polytechnic University, and its remaining officers are all from the PRC.

The issue of Han unification serves to illustrate a fundamental distinction made by Unicode and ISO/IEC 10646, that between character and glyph. A character is a unit of meaning in a writing system, while a glyph is what one actually sees on the page or on the screen. Thus 'a', 'b', and 'c' are different characters, while 'a' and '*a*' are different glyphs for the same character (see Figure 3).

The distinction is an important one. Characters are the fundamental units where meaning is concerned, and are what are used in processes such as searching, sorting, pattern matching, or text to speech. They are insufficient for more visually oriented processes such as printing or optical character recognition. Scripts such as Arabic, for example, make extensive use of contextual forms, where a letter changes its shape depending on its position in a word. If each of the different forms for each letter were separately encoded, not only would that make text input and

Distinct characters: a ɐ α ᵘ ɴ क

Distinct glyphs: a a a *a* *a* ɑ

Figure 3 Characters and glyphs.

U+10391

UTF-16: 0041
UTF-32: 00000041

Figure 4 Unicode encoding forms.

spelling checking more complex, it would also lock the visual representation of Arabic into one calligraphic style. By separating the encoding of the characters from the drawing of the glyphs, it's possible for the same text to have substantially different appearances, depending on additional information such as font and point size.

Unicode is thus aimed at plain text rendering; its goal is minimal legibility – the minimum amount of information needed to guarantee legibility. Pure Unicode should be legible to users regardless of the details of the rendering process.

Unicode defines three character encoding forms, named after the size of the code unit they use: UTF-8, UTF-16, and UTF-32 (see Figure 4). ('UTF' can be taken to stand either for 'universal transformation format' or 'Unicode transformation format.') In UTF-8, each character is represented by one to four bytes. The 128 characters from ASCII are, in fact, represented by the same bytes as they are for ASCII itself. This is an enormous advantage for software originally written for ASCII or other character sets sharing its basic architecture. UTF-16 corresponds to the original definition of Unicode. Characters U + 0000 through U + D7FF and U + E000 through U + FFFF are represented by one 16-bit unit. Characters above U + FFFF are represented by two 16-bit units, using a combination of two units in the ranges 0xD800 through 0xDFFF. (The scalar values U + D800 through U + DFFF are therefore not used for character encoding.) In UTF-32, each character is represented by its Unicode scalar value, padded to 32 bits.

Finally, Unicode defines five character-encoding schemes based on these three encoding forms. These are necessitated because computers vary in how they combine two bytes into one 16-bit unit.

The Future

Unicode and ISO/IEC 10646 can be considered to have rightfully won their title of **the** universal

character set. Although other character sets continue in use, all work on computer representation of text is now done either in Unicode or in a fashion compatible with it. All major operating systems are being written around Unicode, and most software in development supports it.

Major issues still remain. One is the distinction between character and glyph. Although in most cases, the line between the two is clear, in some it is not. Many of the ideographs being considered for encoding by the IRG, for example, are so obscure that even the experts are not sure which ones are distinct characters. In scripts that are yet to be fully deciphered, such as the Indus Valley script, there is the same problem.

Another issue is diachronicity. With a few exceptions, the scripts encoded in Unicode are modern scripts in current use, which means that the repertoires are relatively well defined, as are the ranges of acceptable glyphs for the characters. When an effort is made to represent a script in use over the course of centuries or millennia, things are not always clear cut. Oracle-bone Chinese is not fully understood, for example, and it's unclear how to coordinate it with modern Chinese.

And there is also the issue of scripts that do not follow the linear approach to layout common to all modern writing systems. Unicode has already expressly disavowed any intention of fully encoding music or mathematics because they are so two-dimensional in layout. Egyptian hieroglyphics, however, are a written representation of human language and should be encoded, although the details are far from clear.

But in the meantime, computer technology has advanced considerably in its ability to represent human languages, over the course of just the past decade. Prior to 1990, it would have been unthinkable to exchange data in virtually any human language virtually anywhere in the world. That, however, is now becoming a reality.

Character versus Content

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

David Kaplan introduced the content/character distinction in his monograph *Demonstratives* (1989a) to distinguish between two aspects of the meaning of (1) indexical and demonstrative pronouns (e.g., 'I', 'here,' 'now,' 'this,' and 'that') and (2) sentences containing them. Roughly, the content of an occurrence of an indexical or demonstrative is the individual to which it refers, and its character is the rule that determines its referent as a function of context. Thus, an indexical has different contents in different contexts, but its character is the same in all contexts. For instance, the character of 'I' is the rule, or function, that maps a context of utterance to the speaker of that context. This function determines that the content of Sally's utterance of 'I' is Sally.

Content/Character Distinction and Semantics

Sentences containing indexicals or demonstratives are context-dependent in two ways. First, contexts help to determine what these sentences say. Second, contexts determine whether what is said is true or false. For instance, suppose Sally says, 'I'm cold now' at time t. The context supplies Sally as the referent for 'I' and time t as the referent for 'now,' so it helps to determine what Sally said. Other facts about the context, specifically whether Sally is cold at time t, determine whether she said something true or false. Different contexts can play these different roles, as they do when we ask whether what Sally said in one context would be true in a slightly different context. A central virtue of Kaplan's semantics is that it distinguishes between these two roles of context. For Kaplan, a *context of use* plays the first role, of

character set. Although other character sets continue in use, all work on computer representation of text is now done either in Unicode or in a fashion compatible with it. All major operating systems are being written around Unicode, and most software in development supports it.

Major issues still remain. One is the distinction between character and glyph. Although in most cases, the line between the two is clear, in some it is not. Character versus Content

C Spencer, Howard University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

David Kaplan introduced the content/character distinction in his monograph *Demonstratives* (1989a) to distinguish between two aspects of the meaning of (1) indexical and demonstrative pronouns (e.g., 'I', 'here,' 'now,' 'this,' and 'that') and (2) sentences containing them. Roughly, the content of an occurrence of an indexical or demonstrative is the individual to which it refers, and its character is the rule that determines its referent as a function of context. Thus, an indexical has different contents in different contexts, but its character is the same in all contexts. For instance, the character of 'I' is the rule, or function, that maps a context of utterance to the speaker of that context. This function determines that the content of Sally's utterance of 'I' is Sally.

Content/Character Distinction and Semantics

Sentences containing indexicals or demonstratives are context-dependent in two ways. First, contexts help to determine what these sentences say. Second, contexts determine whether what is said is true or false. For instance, suppose Sally says, 'I'm cold now' at time t. The context supplies Sally as the referent for 'I' and time t as the referent for 'now,' so it helps to determine what Sally said. Other facts about the context, specifically whether Sally is cold at time t, determine whether she said something true or false. Different contexts can play these different roles, as they do when we ask whether what Sally said in one context would be true in a slightly different context. A central virtue of Kaplan's semantics is that it distinguishes between these two roles of context. For Kaplan, a *context of use* plays the first role, of

e	c^1	c^2	c^3
u^1	T	F	T
u^2	F	F	F
u^3	T	T	T

Figure 1 Two-dimensional matrix.

supplying contents for indexical expressions, and a *circumstance of evaluation* plays the second. A context of use is just a context in which an indexical expression may be used, and which supplies a content for the indexical expression. A circumstance of evaluation is an actual or merely possible situation in which the content of an utterance is evaluated for truth or falsehood.

A semantic framework like Kaplan's, which captures the double-dependence of meaning on context, is sometimes called a two-dimensional semantics. In the two-dimensional framework, a meaningful entity such as a linguistic expression or an utterance determines not a single semantic value but a two-dimensional matrix of semantic values. **Figure 1** represents Kaplan's semantics in this way. In **Figure 1**, the vertical axis of the matrix displays contexts of use (u^1-u^3) and the horizontal axis displays circumstances of evaluation (c^1-c^3). Each cell in the matrix gives the extension of the linguistic expression *e* as used in the specified context of use and evaluated in the specified circumstance of evaluation. In this matrix, the cell in row *n* and column *m* gives the semantic value of *e* in the context of use specified at the beginning of row *n* and evaluated in the circumstance of evaluation specified at the top of column *m*. If *e* is a sentence, cells will be filled in with truth values as illustrated.

Kaplan offers a syntax and semantics for a formal language containing indexicals, demonstratives, and a variety of modal operators. In this formal system, a context of use is an ordered n-tuple of contextual features to which indexicals or demonstratives are sensitive, such as the speaker, time, world, and location of the context. A circumstance of evaluation is an ordered n-tuple of a possible world-state or world-history, a time, and perhaps other elements as would be required given the sentential operators in the language. For Kaplan, all contexts of use are *proper,* which means that the speaker of the context must be located at the time, place, and world of the context. Circumstances of evaluation, however, need not be proper.

Contexts of use and circumstances of evaluation play a role in the specification of the character and content of an expression. The character of any linguistic expression *e* is a function from contexts of use to contents appropriate for *e*, i.e., an individual if *e* is a singular term, a proposition if *e* is a sentence, and sets of n-tuples of individuals if *e* is an n-place predicate. Indexical expressions only have contents relative to a context of use. So Kaplan speaks of the content of an occurrence of an expression rather than the content of the expression itself. Contents are evaluated in circumstances of evaluation, and these evaluations yield extensions appropriate to the kind of content under evaluation. So we also can characterize the content of an occurrence of *e* as a function from circumstances of evaluation to extensions of a type appropriate to *e*. For instance, the extensions for sentences are truth values, for indexicals, individuals, and for n-place predicates, n-tuples of individuals. For individuals and n-place predicates, these will be constant functions (i.e. the function delivers the same extension in every circumstance of evaluation). It is often simpler to think of contents as individuals (for singular terms), propositions (for sentences) and sets of n-tuples of individuals (for n-place predicates), and Kaplan typically talks about contents in this way. Both ways of thinking of contents are semantically equivalent.

For Kaplan, indexicals and demonstratives are both directly referential and rigidly designating. They are directly referential because they contribute only their referents to the propositions expressed by sentences containing them. They are rigidly designating because, once they secure a content in a context of use, they retain that content in every circumstance of evaluation. Indexicals and demonstratives contrast with the typical definite description in both respects. Definite descriptions typically contribute a descriptive condition to a proposition rather than an individual, and this descriptive condition is typically satisfied by different individuals in different worlds of evaluation. Although Kaplan's view that demonstratives are directly referential is widely accepted, some recent discussions of complex demonstratives (i.e. expressions of the form 'that F') have defended a quantificational approach, and some considerations in favor of such an approach may apply to the pure demonstratives 'this' and 'that' (King, 2001).

Kaplan's semantics has technical virtues lacking in earlier treatments of natural language indexicality. It shares with other double-indexing accounts (Kamp, 1971) a technical superiority to single-index theories, which evaluate sentences relative to a single index, which is an ordered n-tuple of features of a context, such as a speaker, time, location, and world. Such theories cannot account for the interaction of indexicals and certain sentence operators. To evaluate the sentence (1), for instance, we need to consider the truth value of the constituent sentence,

'the man who is now President of the United States no longer hold[s] that office' in situations occurring *after* the sentence is uttered.

(1) Someday, the man who is now President of the United States will no longer hold that office.

But the indexical 'now' in that constituent sentence must still refer to the time (1) is used, and not the time at which the constituent sentence is evaluated. As Hans Kamp has argued, only a double-indexing theory will correctly predict the truth conditions for (1) (Kamp, 1971).

Content/Character Distinction and Philosophy

The content/character distinction sheds light on some specifically philosophical issues involving context-sensitivity in thought and language. These applications involve philosophically significant assumptions, and are more controversial than the applications to the semantics of indexicals and demonstratives.

First, content and character play two roles that Gottlob Frege initially envisioned for the meaning, or sense, of a sentence, one semantic and the other more broadly psychological (Frege, 1892). Frege thought that the sense of a sentence should both determine its truth condition and provide the cognitive significance of beliefs expressible with that sentence. Although Frege expected that one entity, the sense, could play both roles, indexical and demonstrative belief undermines this expectation, since it appears to require two different entities to play the two roles. Different people who have a belief they could express by saying 'I'm cold' will be in the same psychological/functional state. They will all be shivering and trying to get warmer. But because each person who thinks, 'I'm cold' is a constituent of the content of that thought, all of these thoughts will differ in content. The psychological role of an indexical belief appears to be more closely tied to the character of the sentence the thinker would use to express that belief than to the content of the belief. But the content, rather than the character, is more directly relevant to the truth condition of an occurrence of a sentence containing an indexical.

Second, Kaplan has suggested that the content/character distinction helps to explain the relation between the epistemological notions of logical truth and the *a priori*, on the one hand, and the metaphysical notions of necessity and contingency on the other. Other philosophers have put broadly similar applications of the two-dimensional framework into service to the same end (Stalnaker, 1978, cf. Stalnaker, 2004; Chalmers, 1996; Jackson, 1998). As is evident to anyone who understands sentence (2), it cannot be uttered falsely. Therefore, sentence (2) is in a certain sense a logical or *a priori* truth. Yet it does not express a necessary truth, since occurrences of (3) will typically be false.

(2) I am here now.

(3) Necessarily, I am here now.

Kaplan has suggested that we explain the special status of (2) as follows: metaphysically speaking, (2) is contingently true in virtue of its content. But it has its special epistemic status in virtue of its character: the character of (2) requires that it express a truth in every context of use. Other sentences which may express the same content as a particular occurrence of (2), but a different character, such as (4), do not have the same special epistemic status.

(4) GWB is in Washington, DC on June 16, 2004.

Because (4) and some occurrences of (2) share a content but differ in their epistemic status, it is natural to conclude that contents cannot be the bearers of this special epistemic property. Critics of this account of the *a priori* (Soames, 2005) say that the content/character distinction cannot underwrite the general account of *a priori* knowledge that some of its defenders (Chalmers, 1996; Jackson, 1998) have claimed.

Third, some philosophers have used Kaplan's content/character distinction to distinguish narrow content (i.e. content determined by the internal state of the thinker) from wide content (i.e. content determined by the internal state of the thinker and his or her environment) (Fodor, 1987; see also Chalmers, 1996; Jackson, 1998, for a related application of two-dimensional semantics to these ends). They suggest that narrow content is loosely modeled on Kaplan's characters, and wide content on Kaplan's contents. That characters seem to capture something important about the psychological roles of belief makes them particularly attractive candidates to model the purely internal aspects of thought. Critics of the approach contend that although characters help to characterize internal states of thinkers, they are not themselves determined by such states (Stalnaker, 1989).

Chart Parsing and Well-Formed Substring Tables

S G Pulman

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 2, pp. 505–508, © 1994, Elsevier Ltd.

For efficiency, most practical parsing algorithms (*see* **Parsing: Statistical Methods**) are implemented using a 'well-formed substring table' (wfsst) to record parses of complete subconstituents. This means that duplicate paths through the search space defined by the grammar are avoided. Since there may be many such paths, use of such a table can sometimes mean the difference between processing time of seconds, as opposed to minutes or even hours.

Well-Formed Substring Tables

To illustrate the notion of a well-formed substring table, consider the process of parsing a sequence analyzable as:

(1) ...(1) V (2) NP (3) PP (4)

(e.g., '...saw the man in the park'), given rules in the grammar like:

(2) VP → V NP
VP → VP PP
NP → NP PP

In a top-down parsing regime, there will be two points at which the first of these rules will be used to predict an NP beginning at position 2. One should assume that the algorithm first finds the nonrecursive NP from 2 to 3. Now, via the third rule, it will again look for an NP, this time followed by a PP. The naive algorithm might repeat the same sequence of actions it has just performed in recognizing the original NP from 2 to 3.

However, if it is assumed that, whenever a complete constituent is recognized, it is recorded in a table, then the algorithm can be changed to consult this table whenever it is looking for a constituent of a particular type at a given point. In this instance, there is already an NP from 2 to 3; therefore, it is possible to proceed directly to look for a PP beginning at position 3.

Having found this PP, it is possible to assemble two VPs: one from 1 to 3, of the form [VP [V NP]], and one from 1 to 4 of the form [VP [V [NP [NP PP]]]].

Now the situation is reached where the second rule predicts a PP beginning at position 3. The naive algorithm will again go ahead and recompute the sequence of actions leading to the recognition of the PP. However, using the wfsst, the fact is already recorded that there is a PP from 3 to 4, and instead the algorithm can simply use that information to build a VP from 1 to 4 of the form [VP [VP PP]]. Thus, at least two recomputations have been avoided. If this does not sound very impressive, the reader is invited to work through the steps involved in parsing a sequence like:

(3) V NP P NP P NP P NP

(e.g., 'saw the man in the park with a telescope on Friday') given the above rules, along with P → P NP, and to check how many times the same constituents

Chart Parsing and Well-Formed Substring Tables

S G Pulman

© 2006 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 2, pp. 505–508, © 1994, Elsevier Ltd.

For efficiency, most practical parsing algorithms (*see* **Parsing: Statistical Methods**) are implemented using a 'well-formed substring table' (wfsst) to record parses of complete subconstituents. This means that duplicate paths through the search space defined by the grammar are avoided. Since there may be many such paths, use of such a table can sometimes mean the difference between processing time of seconds, as opposed to minutes or even hours.

Well-Formed Substring Tables

To illustrate the notion of a well-formed substring table, consider the process of parsing a sequence analyzable as:

(1) ...(1) V (2) NP (3) PP (4)

(e.g., '...saw the man in the park'), given rules in the grammar like:

(2) VP → V NP
VP → VP PP
NP → NP PP

In a top-down parsing regime, there will be two points at which the first of these rules will be used to predict an NP beginning at position 2. One should assume that the algorithm first finds the nonrecursive NP from 2 to 3. Now, via the third rule, it will again look for an NP, this time followed by a PP. The naive algorithm might repeat the same sequence of actions it has just performed in recognizing the original NP from 2 to 3.

However, if it is assumed that, whenever a complete constituent is recognized, it is recorded in a table, then the algorithm can be changed to consult this table whenever it is looking for a constituent of a particular type at a given point. In this instance, there is already an NP from 2 to 3; therefore, it is possible to proceed directly to look for a PP beginning at position 3.

Having found this PP, it is possible to assemble two VPs: one from 1 to 3, of the form [VP [V NP]], and one from 1 to 4 of the form [VP [V [NP [NP PP]]]].

Now the situation is reached where the second rule predicts a PP beginning at position 3. The naive algorithm will again go ahead and recompute the sequence of actions leading to the recognition of the PP. However, using the wfsst, the fact is already recorded that there is a PP from 3 to 4, and instead the algorithm can simply use that information to build a VP from 1 to 4 of the form [VP [VP PP]]. Thus, at least two recomputations have been avoided. If this does not sound very impressive, the reader is invited to work through the steps involved in parsing a sequence like:

(3) V NP P NP P NP P NP

(e.g., 'saw the man in the park with a telescope on Friday') given the above rules, along with P → P NP, and to check how many times the same constituents

are reparsed when a wfsst is not being used. For constructions like this, the numbers can grow very rapidly indeed. Use of a wfsst here is essential if parsing algorithms are to be implemented in a practically usable form.

Another technique is to keep a record of subconstituents that have not been found beginning at a particular point in the input. For example, in the earlier 'saw the man in the park' example, when the VP of the form [VP V [NP [NP PP]]] is found, it will, via the second rule, cause a prediction of a PP beginning at position 4. This prediction fails, because it is at the end of a sentence. When the VP of the form [VP [VP [V NP]] PP] is found, it too will cause the same prediction, via the same rule. Although in this case discovering that there are no more PPs is fairly trivial, this will not always be so, and a lot of recomputation can be saved by also checking that, when looking for a constituent C at position P, one has not already tried and failed to find C at P.

Basic Chart Parsing

A 'chart' is a generalization of a wfsst in which incomplete constituents are also represented. Charts are the basis on which many parsing algorithms are implemented, and they provide a flexible framework within which different types of processing regimes and different types of grammatical formalism can be handled.

A chart consists of a set of 'edges' and 'vertices.' Vertices represent the positions between words in an input sentence, and edges represent partial or complete analyses. An edge, at least when context-free rules or related formalisms are involved, can be thought of as something derived from a rule and having the following structure:

(4) edge(Id, LeftVertex, RightVertex, MotherCat, DaughtersFound, DaughtersSought)

In describing charts it is convenient to use a PROLOG-like notation: Words in lower case are constants, words beginning with upper case are variables, an underscore is a variable whose value is not of interest, and a list of items is enclosed in square brackets, with the convention that an expression like [Head | Tail] represents a list whose first member is 'Head' and whose remaining members (a list) are 'Tail.' An edge has an identifier and connects vertices. DaughtersFound will usually be represented in terms of a list of other edges representing the analysis of those daughters. Daughters Sought is a list of categories. An edge is *complete* if DaughtersSought is empty.

To specify a particular instantiation of a chart framework, it is necessary to state the following:

1. a regime for creating new edges
2. a way of combining two old edges to form a new edge
3. access to an 'agenda' of edges created by (1) or (2) that are waiting for further processing when they are entered into the chart

A Bottom-Up Chart Parser

One particular chart-based algorithm can be specified as follows: It proceeds bottom-up, one word at a time.

(5) New edges:
whenever there is a complete edge put in the chart of the form edge(Id, From, To, Category, -,-) then for each rule in the grammar of the form Lhs → Rhs where Category is the first member of Rhs,
put a new edge on the agenda of the form edge(NewId, From, From, Lhs, [], Rhs)

Not all rules in the grammar meeting this criterion will lead to a complete parse. This step of the procedure can be made sensitive to information precomputed from the grammar so as to select only rules that are, say, compatible with the next word in the input, or alternatively, compatible with the next category sought of at least one incomplete edge ending at the point where the current word starts (see Aho and Ullman, 1977 for various types of relevant grammar relations).

(6) Combine Edges:
Whenever a new edge is put into the chart of the form: edge(Id1, B, C, Cat1, Found1, [])
then for each edge in the chart of the form: edge(Id2, A, B, Cat2, Found2, [Cat1 | OtherDaughtersSought])
create a new edge edge(Id3, A, C, Cat2, [Id1/Found2] Other DaughtersSought)
Whenever a new edge is put into the chart of the form: edge(Id1, A, B, Cat1, Found1, [Cat2 | RestSought])
then for each edge in the chart of the form: edge(Id2, B, C, Cat2, Found2, [])
create a new edge edge(Id3, A, C, Cat1, [Id1/Found1] RestSought)

The first part of 'combine edges' is triggered by the addition of a complete edge to the chart, and produces a new edge for each incomplete edge ending where

the complete edge begins that can combine with it. These incomplete edges are already in the chart. The new edges are put on the agenda.

The second part is triggered by the addition of an incomplete edge to the chart, and produces a new edge for each complete edge beginning where the incomplete edge ends. These new edges are put on the agenda.

Looking at things from the point of view of a complete edge, the first part of 'combine edges' ensures that it is combined with whatever is already in the chart that it can be combined with, whereas the second part ensures that it will be combined with any future incomplete edges entering the chart. Thus, no opportunity for combination will be missed, at whatever stage of parsing it arises.

All that has to be done now to specify a complete chart-parsing procedure is to define access to the agenda: either treat the agenda as a stack (last in, first out) in which case the general search strategy will be depth first, or as a queue (first in, first out) in which case the search order of hypotheses will be breadth first. There could also be more complex heuristics ordering edges on the agenda according to some weighting function: This would mean that the highest scoring hypothesis was explored first, independently of the order in which they were generated.

The procedure must also be embedded in some kind of top-level driver, so as to start off the process and to check for complete analyses when the process is ended. The final program, then, might have the following structure:

```
(7) Until no more words:
      create new edges for next word
      do New Edges for these edges.
        Until agenda is empty:
          pop next edge off agenda and put in chart
          do New Edges
          do Combine Edges
    Check for complete edges of desired category
      spanning start to finish
```

Given the following grammar, the algorithm would proceed as follows on the input sentence 'they can fish' (with the words occupying chart positions 1 to 2, 2 to 3, and 3 to 4, respectively):

S → NP VP
NP → they | fish
VP → Aux VP
VP → Vi
VP → Vt NP
Aux → can
Vi → fish
Vi → can

Operation	*Chart*	*Agenda*
new word edge		e1(1, 2, NP, [they], [])
pop	e1	
new edge		e2(1, 1, S, [], [NP, VP])
pop	+e2	
combined el e2		e3(1, 2, S, [e1], [VP])
pop	+e3	
new word edges		e4(2, 3, Aux, [can], []), e5(2, 3, Vt, [can], [])
pop	+e4	
new edge		e6(2, 2, VP, [], [Aux, VP]), e5
pop	+e6	
combine e4 e6		e7(2, 3, VP, [e4], [VP]), e5
pop	+e7	e5
pop	+e5	
new edge		e8(2, 2, VP, [], [Vt, NP])
pop	+e8	
combine e5 e8		e9(2, 3, VP, [e5], [NP])
pop	+e9	
new word edges		e10(3, 4, Vi, [fish], []) e11(3, 4, NP, [fish], [])
pop	+e10	e11
new edge		e12(3, 3, VP, [], [Vi]), e11
pop	+e12	e11
combine e12 e10		e13(3, 4, VP, [e10], []), e11
pop	+e13	e11
combine e7 e13		e14(2, 4, VP, [e4, e13], []), e11
pop	+e14	e11
combine e3 e14		e15(1, 4, S, [e1, e14], []), e11
pop	+e15	e11
pop	+e11	
new edge		e16(3, 3, S, [], [NP, VP])
combine e9 e11		e17(2, 4, VP, [e5, e11], []) e16
pop	+e17	e16
combine e3 e17		e18(1, 4, S, [e1, e17], []) e16
pop	+e18	e16
pop	+e16	
combine e16 e11		e19(3, 4, S, [e11], [VP])
pop	+e19	

At this point, no more processing can take place. Inspecting the chart, it can be found that these are two complete edges (edges 15 and 18) spanning the input of the desired category, S. By recursively tracing through their contained edges, the syntactic structure of the analyses implicit in the chart can be recovered. It can be noticed that, as well as sharing some complete subconstituents (edge 1), the final analyses were built up using some of the same partial constituents (edge 3).

Other Chart-Based Parsing Algorithms

It is easy to formulate different processing regimes within the chart framework. By redefining the 'new

edges' routine to operate on incomplete edges, one can implement a top-down, 'Earley' style of algorithm (Thompson and Ritchie, 1984). Alternatively, it is possible to define 'new edges' so that any arbitrary constituent, rather than the first, is used to build new edges, and with corresponding changes to 'combine edges,' constituents can be built right to left, as well as left to right (Steel and de Roeck, 1987). This can be useful for practical efficiency when some construction is 'keyed' by an item that is not the leftmost one, (e.g., conjunctions in English or verbal complements in subordinate clauses in languages like German). A left-to-right strategy would have to allow for the possibility of many types of constituents before there was any evidence for them, possibly leading to a lot of wasted computation most of the time. This strategy can also be generalized to 'head-driven' parsing, using information from the head of a phrase to guide the search for its sister constituents to the left or right (Kay, 1990).

For all of these different types of parsing algorithms, appropriate search strategies can be imposed by different methods of manipulating the agenda, as mentioned earlier.

Chart parsing also offers a degree of robustness in the case of a failure to find a complete parse, either because the input is ungrammatical or (what amounts to the same thing from the point of view of the parser) is not within the coverage of the grammar. Even if the overall parse fails, an algorithm like the one above will result in all well-formed subconstituents that are present in the input being found. From these, different types of heuristic strategy can be used to do something useful. Mellish (1989) described one such technique, which attempted to massage an ill-formed input into a well-formed one by inserting or deleting constituents after the ordinary parsing process has failed.

It is also worth pointing out that many of the virtues of charts as a basis for parsing are also desiderata for the reverse process of generation. In generation as well as in parsing, it is important to avoid unnecessary recomputation. Shieber (1988) describe that a chart-based framework that was intended to accommodate a variety of generation and parsing algorithms.

Packing

Although charts, as so far described, offer considerable economy of representation and processing, they still take exponential time and space when there is an exponential number of parse trees to be assigned to a sentence. This can be improved on. Notice that in the example above, two VP constituents were built spanning 2 to 4, and these in turn gave rise to two S constituents, each containing the same NP. This has the advantage that all analyses of the sentence are explicitly represented: There is an S edge for each one. However, it has the disadvantage that the combination is done redundantly on the second and any further occasions. (This is where the exponential behavior arises.) If an NP can combine with one VP from 2 to 4 to form a sentence, then it is obvious that it can also combine with any other VP from 2 to 4. At the point at which this move is made, the fact that the two VPs have a different internal structure is irrelevant.

At a cost of extra work in spelling out explicit parse trees when other processing has been completed, this redundancy can be eliminated. In the chart framework developed here, this is most easily achieved by generalizing the representation of complete edges so that the 'constituents' or 'Daughters Found' field is a disjunction of lists of edge identifiers, rather a single list. Then the algorithm must incorporate the extra step, whenever it is building a complete edge, of checking to see whether there is already in the chart a complete edge of the same category and with the same 'from' and 'to' labels. If there is, it can simply make a disjunction of the constituents field of the edge being built with that of the existing edge and no new edge is needed, or anything else. Any analyses that the existing edge already takes part in will also involve the new edge, and the new edge will be included in any further analyses involving the existing edge. Thus, in the case of the second VP edge, at the point where edge 9 can combine with edge 11 to form edge 17, edge 14 would have extended to look like:

e14(2, 4, VP, [[e4, e13], [e5, e11]], [])

Then the combination of edge 3 with edge 14 to make a sentence would represent both analyses, without needing to repeat the combination explicitly. In this case, only one set of operations is saved, but it is easy to see that in cases like the multiple PP sentence encountered earlier, the savings can be considerable.

This extension is essentially the notion of 'packing,' as described in, for example, Tomita (1987). If explicit parse trees are required, then there is an extra cost in a post-processing phase, for each disjunction will need to be unpacked into a separate analysis. This step may be exponential even where parsing time was polynomial: The complexity is moved, not eliminated. However, the number of constituents created and the number of computational operations performed while actually parsing will usually be far smaller if packing is used than if the simple chart scheme is used. Moreover, in many practical NLP

systems, parse trees do not need to be enumerated explicitly, except perhaps for debugging purposes, as they are merely a preliminary to semantic interpretation. In some of these systems (e.g., that described in Alshawi *et al.*, 1988), many aspects of semantic interpretation can be done on packed structures directly, saving yet more computational work.

Chatterji, Suniti Kumar (1890–1977)

K Karttunen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Suniti Kumar Chatterji was born in Sibpur, Howrah on November 26, 1890, and died in Calcutta on May 29, 1977. He was born in a traditional Sāmaveda Brahman family of Kaśyapa clan originating in Eastern Bengal. He was educated at Motilal Sil's Free School, Scottish Church College (B.A. 1911), and Calcutta University (M.A. 1913 in English, then also Sanskrit studies until 1919). In 1913 he became Professor of English at Vidyasagar College in Calcutta, and in 1914–1919 he taught English as an Assistant Professor at Calcutta University.

Chatterji undertook further studies of Indo-Aryan and Indo-European in London in 1919–1921 (D.Litt. 1921 in Indo-Aryan philology, under L. D. Barnett, F. W. Thomas *et al.*) and in Paris in 1921–1922 (under Bloch, Meillet, Przyluski, Pelliot *et al.*). In 1922 he became Khaira Professor of Indian Linguistics and Phonetics at Calcutta University, and in 1952 he was named Emeritus Professor of comparative philology. As a friend of Tagore, he served many years as a member of the governing body of Visva-Bharati University. In the 1950s and 1960s he was Chairman of the Upper House of the West Bengal Legislature. He attended numerous congresses and traveled widely, e.g., around 1951 acting as visiting lecturer at Pennsylvania University for 6 months. He won many honors, e.g., Dr.h.c. in 1960 from Rome and D.Litt.h.c. in 1965 from Delhi. From 1964 on he was National Research Professor of Humanities.

Chatterji's London dissertation, *Origin and development of Bengali,* published in 1926, made him famous as the foremost linguist of India. He was no theoretician but had a good grasp of historical linguistics and discussed questions of Old and Middle Indo-Aryan, Bengali, and Hindi and contacts of Indo-Aryan with other Indo-European and non-Indo-European languages. He was one of the first phoneticians in India. In addition to linguistic works he edited Bengali and Maithili texts and wrote a number of books and essays on such topics as languages, literature, history, national questions, and travel books in English, Bengali, and Hindi. Among his students were M. M. Ghosh and S. Sen.

systems, parse trees do not need to be enumerated explicitly, except perhaps for debugging purposes, as they are merely a preliminary to semantic interpretation. In some of these systems (e.g., that described in Alshawi *et al.*, 1988), many aspects of semantic interpretation can be done on packed structures directly, saving yet more computational work.

Chatterji, Suniti Kumar (1890–1977)

K Karttunen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Suniti Kumar Chatterji was born in Sibpur, Howrah on November 26, 1890, and died in Calcutta on May 29, 1977. He was born in a traditional Sāmaveda Brahman family of Kaśyapa clan originating in Eastern Bengal. He was educated at Motilal Sil's Free School, Scottish Church College (B.A. 1911), and Calcutta University (M.A. 1913 in English, then also Sanskrit studies until 1919). In 1913 he became Professor of English at Vidyasagar College in Calcutta, and in 1914–1919 he taught English as an Assistant Professor at Calcutta University.

Chatterji undertook further studies of Indo-Aryan and Indo-European in London in 1919–1921 (D.Litt. 1921 in Indo-Aryan philology, under L. D. Barnett, F. W. Thomas *et al.*) and in Paris in 1921–1922 (under Bloch, Meillet, Przyluski, Pelliot *et al.*). In 1922 he became Khaira Professor of Indian Linguistics and Phonetics at Calcutta University, and in 1952 he was named Emeritus Professor of comparative philology. As a friend of Tagore, he served many years as a member of the governing body of Visva-Bharati University. In the 1950s and 1960s he was Chairman of the Upper House of the West Bengal Legislature. He attended numerous congresses and traveled widely, e.g., around 1951 acting as visiting lecturer at Pennsylvania University for 6 months. He won many honors, e.g., Dr.h.c. in 1960 from Rome and D.Litt.h.c. in 1965 from Delhi. From 1964 on he was National Research Professor of Humanities.

Chatterji's London dissertation, *Origin and development of Bengali,* published in 1926, made him famous as the foremost linguist of India. He was no theoretician but had a good grasp of historical linguistics and discussed questions of Old and Middle Indo-Aryan, Bengali, and Hindi and contacts of Indo-Aryan with other Indo-European and non-Indo-European languages. He was one of the first phoneticians in India. Chavée, Honoré (1815–1877)

J van Pottelberge, Ghent University, Ghent, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Honoré Chavée, a Belgian comparative linguist who specialized in Indo-European and Semitic languages, initiated the school of naturalist linguistics in France and became one of its main representatives. He was born in Namur (Belgium) on June 3, 1815, and trained as a Roman Catholic priest at the Namur Diocesan Seminary (1833–1838). In 1840 he became parish priest of Floriffoux, but soon quit in 1843, moving to Brussels and eventually to Paris, teaching classes at Stanislas College (1846–1848) that formed the basis for his early magnum opus, *Lexiologie indo-européenne* (1849). Soon afterward he abandoned the priesthood and the Christian faith, embraced Auguste Comte's positivism, and became a Freemason. From 1848 on Chavée taught his students at his home; he gave guest lectures in Pisa and Bologna, and taught German at the *École Polytechnique* in Versailles in 1871–1872. He died after a lingering illness on July 16, 1877.

Apart from his studies of Semitic languages at Leuven under Jan Theodoor Beelen (a biblical exegete and orientalist) from 1838 until 1840 and classes with Eugène Burnouf in Paris, Chavée was essentially self-taught, though influenced by the writings of Frédéric Eichhoff, Friedrich Diez, Franz Bopp, and others. Very much like August Schleicher, with whose work he did not however become acquainted until later, Chavée adopted the view that language is a living organism (and that the loss of transparent morphological structure represents 'illness' or decay), and took a historical and glottogonic approach to comparativism. Throughout his work, he reconstructed primitive monosyllabic roots of language, which consisted of only two classes: syllables expressing sensations (verbs) and demonstrative syllables (pronouns). He considered both kind of etymological roots to be spontaneous creations of the brain and, consequently, regarded linguistics as a branch of anthropology and ultimately as a natural science. Given that comparative research demonstrated the distinct origins of Semitic and Indo-European roots, Chavée drew the conclusion from the polygenetism of the languages that the races who speak them also have a polygenetic origin.

Unlike other comparative work of his time, Chavée's research included (lexical) meaning, as he tried to establish primitive semantic kernels and classified all verbal roots into onomasiological 'natural families' after the model of biological taxonomy. Being over-eager to schematize, however, most of his reconstructions are speculative.

Together with Abel Hovelacque, his most famous pupil, Chavée founded the *Revue de Linguistique et de Philologie Comparée* in 1867 (which appeared until 1916), the first French journal devoted to linguistics and the main dissemination channel of the naturalist school. Apart from his comparative work, Chavée wrote on language education; his descriptions of his native Walloon language are still valuable.

Chibchan

A Constenla Umaña, University of Costa Rica, San José, Costa Rica

© 2006 Elsevier Ltd. All rights reserved.

The Chibchan stock is currently composed of the 16 languages from Central America and northwestern South America listed below with their main current alternate names, approximate number of speakers, and location: Pech (Paya; 900; Olancho Department, eastern Honduras), Rama (20; Rama Cay and other localities south of Río Escondido, southeastern Nicaragua), Maléku Jaíka (Guatuso; 300; Guatuso County, northern plains of Costa Rica), Cabécar (8500; Atlantic watershed and southern Pacific slope of the Talamanca Range, southern Costa Rica), Bribri (6000; southern Atlantic and Pacific slopes of the Talamanca Range), Boruca (Brunka; 2, 20 semi-speakers with a passive domain of the language; Térraba Valley, southwestern Costa Rica), Teribe (a dialect of Naso; 3000; Teribe and Changuinola rivers area, northwestern Panama; Térraba, the Costa Rican dialect, is extinct), Buglere (Bocotá, Guaymí Sabanero; 3700; Bocas del Toro, Veraguas, Chiriquí Provinces, western Panama), Ngäbere (Guaymí; 110 000 in the Bocas del Toro, Chiriquí, and Veraguas provinces, Western Panama, and 2172 in the bordering area of southwestern Costa Rica), Kuna (70 000 in the eastern Atlantic coast and the southeastern Paya and Pucuro localities of Panama, and 800 in Arquía and Caimán Nuevo in the Urabá Gulf, Colombia), Chimila (450; lowlands to the south of Fundación River, Magdalena Department, Colombia), Cogui (Cágaba; 6000; northern, eastern, and western slopes of the Sierra Nevada de Santa Marta, Colombia), Damana (Malayo; 1500; southern and eastern slopes of the Sierra Nevada de Santa Marta), Ica (Bíntucua; 8000; southern slopes of the Sierra Nevada de Santa Marta), Barí (Motilón; 1500 in Colombia, 850 in Venezuela; Serranía de Motilones), and Tunebo (Uwa; 3500, mostly in Colombia, a few in Venezuela; eastern slopes of the Sierra Nevada de Cocuy). Formerly, the stock included at least eight more languages which are listed with their original location, and approximate time of extinction: Huetar (central Costa Rica, 18th century), Chánguena, Dorasque (both in western Panama, Chiriquí Lagoon area, beginning of the 20th century), Antioquian (central and northeastern Department of Antioquia, Colombia, 18th century), Tairona (the coast to the north of the Sierra Nevada de Santa Marta, 18th century or before), Kankuama (eastern slopes of the Sierra Nevada de Santa Marta, first half of the 20th century), Duit (Boyacá Department, Colombia, 18th century), and Muisca (Cundinamarca Department, Colombia, 18th century).

Subgrouping

The following subgrouping is based on both lexicostatistical and comparative evidence (Constenla, 1995: 42):

I. Pech.
II. Core Chibchan:
  IIA. Votic: Rama, Guatuso.
  IIB. Isthmic:
    B1. Viceitic: Cabécar, Bribri.
    B2. Boruca.
    B3. Teribe.
    B4. Guaymiic: Ngäbere, Buglere.
    B5. Doracic: Dorasque, Chánguena.
    B6. Kuna.
  IIC. Magdalenic:
    C1. Core Magdalenic:
      C1.1. Southern Magdalenic:
        C1.1a. Chibcha: Muisca, Duit.
        C1.1b. Tunebo.
      C1.2. Arhuacic:
        C1.2a. Cogui.
        C1.2b. Eastern-southern Arhuacic:
          C1.2b.1. Eastern Arhuacic: Damana, Kankuama.
          C1.2b.2. Ica.
    C2. Chimila.
    C3. Barí.

There are some indications that (a) the Isthmic group could be divided into two branches: Viceitic-Boruca and Teribe-Guaymiic-Doracic-Kuna, (b) the

    C2. Chimila.
    C3. Barí.

There are some indications that (a) the Isthmic group could be divided into two branches: Viceitic-Boruca and Teribe-Guaymiic-Doracic-Kuna, (b) the

Magdalenic group could be also divided into two branches: Southern Magdalenic-Barí and Arhuacic-Chimila, (c) Huetar might belong to Votic, and (d) Tairona to Eastern-southern Arhuacic (Jackson, 1995: 67–68).

The split of Proto-Chibchan into the ancestors of Pech and Core Chibchan occurred, according to glottochronology, around 6550 years BP, at the times of the beginning of the transition from the hunter-gatherer way of life to the agricultural one. The greater diversity between the languages is found to the west and north, in Central America, which suggests that the Chibchan people's homeland must have been there, probably in Costa Rica and Panama, where archeology has found the oldest sites related to them.

External Relationships

There have been proposals of relationships between Chibchan and at least a score of other Amerindian language groups and isolates from Florida in the United States to northern Chile and Argentina (such as Timucua, Tarascan, Cuitlatec, Xincan, Lencan, Misumalpan, Chocoan, Andaquí, Betoy, Warao, Yanomama, Paez, Barbacoan, Mochica, Kunza, Allentiac), which together would constitute a Macro-Chibchan phylum. None of these have been proved, and the quality of the supposed evidence in their favor is extremely poor (Constenla, 1993: 81–95).

Typology

The Chibchan languages belong to the Lower Central American Linguistic Area, characterized by features such as SOV order, postpositions, prepositive genitive, postpositive numerals and adjectives, lack of gender contrasts, and contrasts between voiced and voiceless stops.

The Chibchan languages of southern Costa Rica and western Panama, together with the Chocoan languages, constitute a Central Subarea characterized by the predominance of features such as distinctive vowel nasality, tense/lax vocalic contrasts, ergative or active case systems, and absence of person inflections. Most Chibchan languages in this subarea present numeral classifiers, postpositive demonstratives, and tone contrasts.

Pech, Rama, and Maléku Jaíka are part of a Northern Subarea, and the Magdalenic languages, of an Eastern Subarea. Although each of these subareas possesses its own characteristics, they share the predominance of features, both positive and negative, opposed to those of the Central subarea such as accusative-nominative case systems (Maléku Jaíka and Tunebo are exceptions to this), person inflection for possession in nouns and for agent and patient in verbs, prepositive demonstratives, and lack of numeral classifiers, distinctive vowel nasality, and tense/lax vocalic contrasts.

CHILDES Database

A Theakston, University of Manchester, Manchester, UK

© 2006 Elsevier Ltd. All rights reserved.

Overview of the System

The Child Language Data Exchange System (CHILDES) has revolutionized the way that research is carried out among the child language research community in the 20 years since its inception. The system was first developed by Brian MacWhinney and Catherine Snow and put in place at Carnegie Mellon University in the United States. MacWhinney has remained the driving force behind the development of the system. The CHILDES system consists of three main tools: a system of transcription for linguistic data (CHAT format), a set of tools for analyzing those data when transcribed according to the principles of the system (the CLAN programs), and a database of linguistic corpora provided by members of the language research community for use by the wider research community. All aspects of the system are available online and can be downloaded from the CHILDES homepage. In addition, the CHILDES system supports online access to membership lists and e-mail distribution lists (info-childes) that have encouraged discussion and debate among eminent researchers and new researchers. From its humble beginnings, the system has grown to include corpora from more than 30 languages, covering first-language acquisition, bilingual acquisition, language disorders, and narrative. The transcripts are generated from case studies and from groups of children, and include both longitudinal and cross-sectional data. Although American English and British English are well represented, other languages such as Sesotho, Estonian, Spanish, and Cantonese are included in the database.

A key benefit of the CHILDES system is in providing researchers with a wealth of data on which to base their analyses of children's early language. Due to time and financial constraints, researchers wishing to use longitudinal data have made recordings (traditionally approximately one hour every week) from small numbers of children or even from case studies. This means that it is sometimes difficult to generalize research findings to other children. Researchers are now able to compare the results from their own data with those from other comparable children from the CHILDES database. Indeed, many researchers use the database as the sole source of data for their analyses. However, to use the CHILDES system properly, it is essential to understand the basics of transcription. In addition, as a courtesy to those who donate data, it is necessary to cite an appropriate reference to recognize the researchers who contributed the data used in an analysis. Researchers should also cite the CHILDES handbook (MacWhinney, 2000a, MacWhinney, 2000b) to acknowledge use of the system and to recognize the work of Brian MacWhinney in developing and maintaining the system.

Transcription and CHAT Format

The first major tool of the CHILDES system is the CHAT format for transcription. This is a set of guidelines for transcription that, if followed correctly, enables all researchers who understand the system to accurately interpret any transcripts contributed to the database and to use the data in their analyses. The system is relatively straightforward but takes a bit of time to master. A handbook written by Brian MacWhinney entitled *The CHILDES Project: tools for analyzing talk, Vol. 1* (2000a) provides details of the various aspects of transcription, but readers are advised to consult the online transcription manual for up-to-date information, as the format for transcription is sometimes modified in line with developments in the overall system.

A simple transcript includes *header* tiers that provide background information, for example the participants, the location or setting, the date, and so on. The header tiers are then followed by the transcript. Each *main* line of the transcript represents a separate utterance and is identified by a speaker ID followed by the utterance. Each main line can then be accompanied by any number of *dependent* tiers that appear directly beneath the utterance and allow more detailed coding, for example speech act coding, glosses of second languages, error coding, and any general comments that assist the researcher. All transcripts must finish with a final 'End' line. Figure 1 shows a sample transcript in the CLAN window. The transcript shows headers, main lines, and a few dependent tiers (for errors –%err, and morphological analysis, %mor), and also includes examples of coding for retracings [/], imitations [+ I], unintelligible speech (xxx, [+ PI]), incomplete utterances +//. [+ IN], and omitted material prefaced with 0.).

When transcribing data, transcripts can be made as simple or as complex as is required by the individual researcher. However, as transcription is a lengthy process (often up to 10 hours per hour of data), forward planning is essential to make the most of the time available. It is possible to save a lot of time if sufficient thought is given in advance to the kinds of

Figure 1 A sample transcript (adapted from the Manchester corpus available on CHILDES, Theakston *et al.*, 2001).

questions the researcher might want to ask of the data and the transcript is coded accordingly. Many aspects of linguistic interactions are easy to code as transcription is taking place, but are somewhat harder to locate at a later stage should it be necessary for a given analysis. For example, argument structure overgeneralizations (e.g., *Don't giggle me*) are difficult to locate unless coded as errors, and the identity of omitted words or morphemes may be evident in the context of the recording when intonation patterns are available, but may be unclear when we are faced with the bare transcript. However, the vast range of coding possibilities available and the necessity of selecting among these to address the needs of the immediate research means that when using data available on CHILDES that has been contributed by other researchers, it is essential to ascertain whether the coding carried out is sufficient to support your own specific analyses.

Analysis and the CLAN Programs

Once the researcher has transcripts available for analysis, either through the transcription of new data, or by accessing data online, the second component of the CHILDES system comes into play. The CLAN programs provide a powerful computerized system of analysis for transcripts in CHAT format. There are about 40 programs, although most researchers will find themselves using just a handful. To run the programs, it is necessary to type fairly basic commands into the command window (see Figure 2), and to ensure that this is done accurately, as programs will either not run or will generate inaccurate results if the command is flawed. The most commonly used programs allow automated calculation of standard measures such as mean length of utterance or turn (MLU, MLT), type token ratios and measures of lexical diversity (VOCD, FREQ), and enable researchers to conduct basic frequency counts on words or phonemes quickly and accurately (FREQ, PHONFREQ). More advanced programs allow researchers to isolate utterances containing specific words, word types, or word combinations either alone or with preceding and following linguistic context (KWAL and COMBO). It is also possible to generate co-occurrence data showing the frequency with which individual combinations of words occur together (COOCCUR).

Figure 2 The CLAN commands window.

Those researchers who take the time to fully understand the CLAN programs will be rewarded, as many more complex research questions require the use of a combination of different programs in sequence, using the output of one program as input to another to generate results. Using the CLAN programs can be confusing for the novice, as all programs have a number of switches that allow different output. For example, it is possible to output information with or without line numbers, in alphabetical order, preserving details of file names, or merging all output from several files together. As for transcription, there is a published manual (MacWhinney, 2000a, 2000b) providing guidance on the use of the programs, but readers are advised to consult the online manual, as many programs are regularly updated as the capabilities of the system improve. The manual also provides basic tutorials in the use of the programs.

At the most straightforward level, analyses are carried out on all speakers and on the main line in the transcript. However, it is possible to fine-tune analyses by specifying individual speakers or individual tiers over which to conduct these analyses. Moreover, it is possible to run the programs on single transcript files, or over many files simultaneously, and to generate output file by file, or to merge output together across files and/or speakers. Search commands can be modified to include wildcards to allow more complex analyses. Anyone carrying out analyses using the CLAN programs should check the output against the original files, at least in the first instance, to check that the search is operating in the way expected. Although the programs are powerful and can perform searches quickly and efficiently, the accuracy of the output relies crucially on the accuracy of the transcription, coding, and the search command.

In addition to the analysis programs, the MOR and POST programs allow researchers to add a line of morphological coding to their transcripts. For researchers interested in the development of grammar, these programs provide an extremely valuable tool. Once a transcript has been coded, it is then possible to search for specific word types, for example verbs, pronouns, and for combinations of these items, allowing much more powerful analyses. To date, almost all of the English data in CHILDES has been run through the MOR program by Brian MacWhinney and colleagues, as well as some Spanish, Japanese, and Cantonese corpora. For English, the POST program provides almost fully automated coding (the MOR program alone generates options for grammatical coding, but the choice of the correct coding is largely done by hand). There are currently MOR grammars available for Cantonese, Chinese, Dutch, English, French, German, Italian, Japanese, and Spanish, and grammars are being developed for a number of other languages. Of course, the accuracy of any analysis based on the line of morphological coding depends on the accuracy of the coding itself. Although the grammars are continually being updated, in the past there have been a few problems with the accuracy of the coding, so researchers are advised to check transcripts carefully prior to running any analyses to ensure that the coding is correct.

New Directions

One of the more recent developments of the CHILDES system is the ability to link transcripts to digitized audio and video data. It is necessary to create a digitized sound or video file, but it is then possible to create a direct link between an individual utterance in a transcript and the corresponding section of audio or video recording. This has the potential to revolutionize child language research, as it will allow us to investigate issues that were not considered by the original researchers, by recoding the audio or video data. For example, this may be useful to people interested in phonological development, as few recordings are transcribed phonetically by researchers interested in later language development or the acquisition of grammar. It will also allow researchers to double-check utterances that they are unsure of, for example, children's errors or utterances marked unintelligible by the original transcriber. It is now possible to access linked transcripts for a number of datasets from the CHILDES website and either download these or view them online.

New improvements in technology bring with them potentially difficult issues with respect to participant consent and confidentiality. When parents and children agree to participate in studies of child language acquisition, we have a responsibility to ensure that we obtain consent for all uses of the resulting

data. In the past, parents would not have envisaged transcripts of their interactions with their children appearing on the Internet, available to anyone who cares to look and listen. Traditionally, researchers have dealt with this problem by giving children pseudonyms and removing any potentially identifying information from the transcripts. Of course, this is easy to do with written transcripts, but much more difficult if we intend to make audio and video recordings available online to the wider research community. The availability of audio and video recordings also means a much wider range of questions that may potentially be asked of the data than the original researchers intended, again raising issues of participant consent.

A second ongoing development is the transformation of the CHILDES database into XML format through the Talkbank project. This will eventually allow researchers to access the CHILDES database online and to run analyses directly without having to download the data to their own computers. Of course, many researchers prefer to recode data before analysis, but the facility to run analyses online will doubtless prove useful to many people.

Conclusion

The CHILDES system has led to significant improvements in research in child language acquisition over the last 20 years, and will continue to do so with the new developments taking place. It is a huge benefit to the research community that there are now large amounts of data for English, and increasing amounts of data from a wide range of other languages. However, it is necessary for researchers to exercise caution. First, over-reliance on the CHILDES database can lead to the extensive analysis of data from just a few children, which may bias our findings in various ways. Second, when comparing children using data from CHILDES, it is important to carefully control for the age and linguistic stage of the children concerned, and to ensure that the corpora are comparable in terms of transcription procedures and coding before carrying out any analyses. Third, the increasing trend toward analyses at the lexical level means that although the CHILDES system provides data from many children, relatively few of these children have enough data in a dense enough time period to support such analyses. These issues mean that although the CHILDES database is a valuable resource, it is essential that researchers continue to donate new data to CHILDES to promote rigorous cross-linguistic research into language acquisition.

Children's Literature: Translation of

T Puurtinen, University of Joensuu, Savonlinna, Finland

© 2006 Elsevier Ltd. All rights reserved.

Role and Readership

Translation of children's literature poses particular challenges owing to some special characteristics of children's books and qualities of child readers. The fact that children's literature tends to have a peripheral position in cultures (Shavit, 1986) and suffer from lack of prestige makes it possible to manipulate texts translated for children in various ways to make them accord with the expectations of the receiving culture. Furthermore, children are not expected to tolerate as much strangeness and foreignness as adult readers, and therefore, modification of the content and language of source texts is often considered necessary. Instead of being innovative, translated children's books thus tend to conform to conventional, accepted forms, models, and language. However, children's literature plays an important part as a tool for education, socialization, development of linguistic skills, and spreading world knowledge. Especially in minor language cultures, where translations account for a large proportion of published children's literature, children are likely to come into contact with literature and its educative and entertaining functions mainly through translations. Therefore, translations may have a key role in introducing child readers to characters, events, and language typical of fiction.

The term 'children's literature' usually refers to fiction targeted at readers from preliterate children to young teenagers; nonfiction, such as school textbooks, is excluded. Children's fiction is, in fact, not a uniform genre either; its various subgenres, e.g., fairy tales and fantasy stories, detective novels, realistic stories, differ in terms of purpose and language (see Puurtinen, 2003: 402), which is likely to affect the choice of translation methods. Here, however, children's fiction is treated as one, albeit very heterogeneous, genre.

Although children are the primary readership, children's books actually have an important secondary target group – adult readers, whose preferences and literary tastes must be taken into account by both authors and translators. However, Oittinen (1993, 2000) advocates translating **for children**, rather than translating children's literature, and emphasizes the significance of children's culture and their magical world, as well as society's image of childhood and the translator's own child image (Oittinen, 2000: 41–60).

In addition to the existence of two target groups, children's literature has a number of other special qualities, which have an effect on both the content and language of translations: strong ideological, didactic, ethical, and moral norms, ambivalence, aim at high readability and speakability, and text–picture relationship. (Nikolajeva, 1996, is an extensive discussion of features and forms of children's literature.) Translation problems and their solutions made at the level of language tend to reflect, and result from, these hierarchically higher levels. (For a comprehensive review of studies on the translation of children's literature, see Tabbert, 2002.)

Cultural Norms

Various norms regulating the translation of children's literature can be subsumed under the more extensive concept of culture, or ideology in a neutral sense, referring to taken-for-granted assumptions, beliefs, and values shared by a particular society or culture. In fact, ideology is the overriding constraint, an umbrella concept, dictating what is acceptable children's literature (see Stephens, 1992; Knowles and Malmkjær, 1996). In general, children's books are expected to be in some way beneficial to children and sufficiently easy in terms of plot, characterization, and language to be comprehensible (Shavit, 1981: 172, 1986: 112–128). These two requirements may sometimes be contradictory. For instance, a maximally understandable text may be regarded as too simple to teach anything new and, in that respect, benefit the child reader. Moreover, notions of what is beneficial and comprehensible vary from culture to culture and change with time, which often leads to manipulation of source texts in translation (see Shavit, 1981, for examples of manipulation, and Desmidt, 2003, for didactic norms and readability).

A good example of the effect of strong didactic norms on language is the French translation of *Pippi Longstocking,* the originally Swedish *Pippi Långstrump* by Astrid Lindgren. While the original Pippi shows disrespect towards adults in her anarchic, norm-breaking language use, the French translation has turned her into a more obedient, well-behaved girl by, e.g., toning down impolite expressions (Heldner, 1993). Another example of didacticism is provided by the older German (German, Standard) translations of Tove Jansson's originally Swedish *Moomintroll* books, which have, e.g., omitted references to kissing, poker games, and American dance music, because these were considered unsuitable for German children's literature in the 1950s, at the time

of publishing the translations (Bode, 1996; for censorship in East Germany, see Thomson-Wohlgemuth, 2003).

Ambivalence

The need to appeal to adult readers leads to the creation of ambivalent texts, which can be read and interpreted differently by children and adults (Shavit, 1986: 63–91). Well-known classics, such as Lewis Carroll's *Alice's adventures in wonderland* and Kenneth Grahame's *The wind in the willows,* are examples of ambivalent texts, which children are supposed to read on only one level, as simple fairy tales, whereas adults are expected to be aware of the ironical or satirical levels as well. Intertextuality, such as allusions to other literary texts, films and real-life or fictional characters, is a typical element of ambivalence intended to please the more knowledgeable adult audience. When translated, an ambivalent children's book may be simplified and directed merely to children by omitting all ingredients of ambivalence; sometimes two different translations can be made, one for children and the other, retaining ambivalence, primarily for adults.

Readability and Speakability

All special features and norms typical of children's literature are naturally to some extent manifest in the language used, but the feature which is the most directly related to linguistic details is readability, or comprehensibility. Although readability is also influenced by other factors than purely linguistic ones (e.g., such text-external factors as the reading situation, the reader's subject and world knowledge, interest, and motivation), it is usually defined as a textual quality determined by the level of linguistic difficulty. The main determinants of readability include the length and complexity of sentences and the length and familiarity of words (Puurtinen, 1995: 104–115, 135–164; see also Puurtinen, 1997, for syntactic norms). Readability can be understood to cover speakability, the ease of reading aloud, which is an important quality in children's books read aloud by adults to small children (see Puurtinen, 1995: 164–178; Dollerup, 2003). In addition to lexical and syntactic features relevant to readability, speakability is also affected by, e.g., rhyme, rhythm, and alliteration, which make reading aloud fluent and pleasant.

If readability requirements in the source and target literatures are different, the translator may, e.g., simplify sentence structures, decrease sentence length, or use more familiar, concrete vocabulary. The age of the potential readers is crucial, as the reading skills of different age groups vary extensively. The educative function of children's literature and aim at high readability in translation may sometimes be contradictory: Culture-specific elements, such as references to foreign places and customs, convey information about foreign cultures if retained in translation, but they also reduce readability. If, on the other hand, such elements are replaced with familiar, domestic ones, i.e., if cultural adaptation is carried out, readability is increased, but the opportunity to improve knowledge is simultaneously lost. (For preservation, neutralization, and adaptation of culture-specific elements, see, e.g., Klingberg, 1986; Nord, 1993.) In Israel, the desire to teach children the highly valued literary form of Hebrew through literature resulted in a translation policy which forced translators to turn even colloquial source text dialogues into standard, formal Hebrew (Even-Zohar, 1992). Easily understandable, everyday source text language was thus replaced with the traditional, varied, but less readable Hebrew variant. Since the 1980s, didactic intentions have been giving way to considerations of readability in Hebrew children's literature (Du-Nour, 1995).

In some cases high readability may clash with the aim to create an inspiring, enjoyable translation. The numerous descriptive personal names in the *Harry Potter* books (e.g., Neville Longbottom, Minerva McGonagall, Vindictus Viridian) are complicated enough to have a negative effect on readability, but as they often refer to some special qualities of the characters and require inferences and interpretation from the reader, they are likely to make the reading process more active and enjoyable. Therefore, most translators tend to choose such target language equivalents for the names that also trigger inferences (Davies, 2003; for functions and translation of proper names in children's literature, see Nord, 2003).

Relationship between Text and Illustrations

The relationship between text and illustrations is particularly important in picture books for small children, where pictures are the dominant element. In illustrated books for older children, pictures may also have a central role in supporting the text. There is interaction between words and pictures. Pictures influence the interpretation of the content of the story, and words create a point of view to the pictures (Oittinen, 1993: 113–139, 2000: 100–114, 2001, 2003). Thus, the translator's interpretation of the story is affected by the pictures, and this interpretation is reflected in the formulation of the translation. Although translators try to make the text and

illustrations cohere, discrepancies are sometimes created if, e.g., the translator has to work on the basis of the verbal text only, or if the translator is provided with new pictures different from the original ones. To improve correspondence between text and pictures, the translator may also deviate from the text of the original (Dollerup, 2003: 88). However, the original balance between text and pictures can be disturbed, if the translator adds such information into the target text which in the original is only conveyed by pictures (see Tabbert, 1991; O'Sullivan, 2000: 287–291). Translating illustrated texts requires specialized knowledge of the text–picture relationship, child readers' picture reading abilities, and potential cultural differences in the conventions of illustrated books.

Chile: Language Situation

A Valencia, University of Playa Ancha, Valparaiso, Chile

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Chile is situated in the southwest of South America. After gaining independence from Spain, it became an independent republic in 1810. Its geography is uneven and mountainous with a surface of 756 626 sq km, out of which 379.9 sq km are islands. With 15 116 435 inhabitants (census of 2002), Chile is a country with a stable economy and has become one of the most powerful countries of South America, with great human potential as well as potential natural resources and natural beauties.

The official language is Spanish, but there are also minority languages. Autochthonous languages include Mapudungún, Aymara, Rapanui, and Qawásqar, the language of the last representatives of the ethnic group known as Alacalufe. A number of foreign languages are spoken, resulting from successive migrations during the 19th century that were facilitated by the structure of the territory: 4300 km of coastline and innumerable geographical irregularities that generate relatively isolated spaces. All this has influenced the linguistic evolution of the country and, as a consequence, Chile is today a multilingual and pluricultural country.

The education is in Spanish; however, second languages are taught, notably English, but also German (German, Standard), French, Italian, Hebrew, and Japanese.

Spanish Spoken in Chile

The Spanish spoken in Chile is a dialect of the Spanish language and includes characteristics that are also present in other dialects of Spanish, but it is set apart by the frequency in the use of some forms.

Phonologically, Chilean Spanish is, like other South American dialects of Spanish, characterized by *seseo* (that is, European Spanish /θ/ is pronounced /s/). For example, *zapato*, 'shoe', is pronounced [sapáto], as opposed to European Spanish [θapáto]. *Yeísmo* (/λ/ is pronounced /ĵ/); *caballo*, 'horse,' is pronounced [kaßáĵo]. Other features in the speech found in varieties of Chilean Spanish are the aspiration or elision of /s/ in coda position (e.g., [á^{h}no] for *asno*, 'donkey'), and lenition or elision of intervocalic /d/ (e.g., [aláðo] ~ [alá:o] for *alado*, 'winged').

In morphology and syntax, a distinct feature of Chilean Spanish is the use of definite articles before first names, especially with female names (e.g., *la Maria*). These are used less frequently with male names (e.g., *el Juan*), and not with family names (e.g., #*la González*). In tense-aspect morphology, future tense is often formed with a periphrastic construction with *ir a* ('go to') plus infinitive, e.g., *voy a amar*, 'I will love,' instead of the synthetic *amaré*. Another relevant phenomenon related to the forms of address is the one known as '*voseo*,' a phenomenon that, in Chile, has a verbal character: VERB2*psing* + PRON *tú*. In this way, the canonical forms *"tú cantas, tú quieres, tú ves"* [kántas, kjéres, bes] 'you sing, you like, you see' are pronounced "*tú cantai*, *tú querí(h)*, *tú veí(h)*" [kantái, keríh, βeíh]. The use of the pronoun *vos* is stigmatized. Although the phenomenon of *voseo* does not exist in formal speech, this is quite common in colloquial speech as a sign of 'familiarity' between speaker and hearer. Similarly, *ustedes* replaces *vosotros*, and *os* is not used at all.

On the lexical level, Chilean Spanish includes several loanwords from Amerindian languages, e.g., *guata*, 'belly,' *chuncho*, 'owl,' *laucha,* 'little mouse,' and *pololo*, 'boy friend' from Mapudungún; and *camanchaca*, 'mist,' and *calato*, 'naked,' from Aymara. In addition, there are loanwords from European languages such as *kuchen*, 'cake,' *pizza*, and *sandwich*. There is an increasing influence of English, especially in sport-slang, economy, and business. Specific uses in informal speech include *huevón* [weßón], 'fool,' used as an emphatic term of address, as well as *gallo*, 'cock,' for 'man,' *cabro*, 'goat,' for 'boy,' and *cabra*, 'she-goat,' for 'girl.' This is why it is not strange that, as a humorist once said, "*En Chile los gallos se casan con las cabras*" ('In Chile roosters marry goats').

Autochthonous Languages

Mapudungún is the language of the about 1 000 000-strong Mapuche ethnic group. The smaller groups of Pehuenches and Huilliches also belong to this ethnic group and speak languages similar to Mapudungún. Mapudungún (also called Mapuche or Araucanian) is an SVO language. The Mapuche population is predominantly bilingual Mapudungún-Spanish, but has managed to maintain its linguistic identity, despite the violent process of acculturation and economic control suffered from the 16th century onwards. Mapudungún has been studied since the 17th century. In 1992, Adalberto Salas published *Mapuche or Araucanian: phonology, grammar and analysis of texts*, the most complete and modern work on this language.

Chilean Aymara is spoken by approximately 40 000 people in small villages in valleys of the mountain range and high plateau strip in the northern part of Chile, at altitudes of 3000–3800 m. Little work has been done on Chilean Aymara. It is an agglutinative language with a large amount of affixes. The phonological and lexical variations detected until now indicate that it is a variety of the Bolivian Aymara. The Chilean group has developed a form of Aymara-Spanish bilingualism of its own kind.

Rapanui, or Pascuense, is an Austronesian VSO language spoken by approximately 2400 speakers on Easter Island, an island about 3700 km off the Chilean coast. The important and enigmatic archaeological history of this island is responsible for a great flow of tourism and multinational research, which favors the multilingual activity of the island's inhabitants. Bilingual Spanish-Rapanui education is offered in primary and secondary education. Many students continue their studies in universities in continental Chile. There are a number of studies on Rapanui, and there are descriptions of the current language being developed.

Fuegian Languages

Of all the languages once spoken in the inhospitable Chilean Patagonia, the languages of the Ona (or Selk'nam) became extinct in 1928, and of the Yámana or Yagan, in 2003; only a small community of about 20 Qawásqar or Alacalufes persists. There are linguistic studies that have been developed and others still in development, before the inevitable extinction of these languages.

Conclusion

The Spanish spoken in Chile is a peripheral dialect in relation to the rest of the Spanish-speaking world. It has evolved by preserving archaisms and developing a creativity with its own rules. It is in contact with two vernacular Indoamerican languages and one Austronesian language. With current globalization, it is also experiencing a notable increase of anglicisms.

As for the autochthonous languages, there are initiatives with the Department of Education and university researchers for their study and conservation. It is interesting to note the active participation of the young people of these groups. The promulgation of the Indigenous Law – though a great part of these declarations remain effective only on paper – in some way has given place to the recognition of the autochthonous people. In contact areas, some schools give primary education in minority languages. Alphabets have been created for these languages and several universities are preparing teachers for a bicultural and bilingual education.

China: Language Situation

D Bradley, La Trobe University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

China is known in Chinese as *Zhongguo* 'middle nation,' and indeed the cultural influence of China and the Chinese on all its neighbors has been profound. Chinese has been the dominant language of China for millennia, but many other languages are spoken in China. The languages of China fall into ten main groups:

1. Sino-Tibetan, including Sinitic (Han Chinese, the majority nationality) and Tibeto-Burman (17 nationalities, more than 100 languages) throughout the country;
2. Manchu-Tungus (Manchu, Xibo, Ewenk, Oroqen and Hezhe nationalities, seven languages) mainly in the northeast;
3. Mongol in the north central region (5.5 nationalities, including half of the Yugur, seven languages);
4. Turkic (6.5 nationalities and seven languages, with the other half of the Yugur);
5. Austro-Asiatic or Mon-Khmer in the far southwest (Wa, Bulang, De'ang, and Jing nationalities, plus some small unclassified groups, more than 12 languages);
6. Tai-Kadai in the southwest (nine nationalities, more than 20 languages);
7. Miao-Yao in the southwest central area (Miao, Yao, and She nationalities, 27 languages);
8. Indo-European (two nationalities, Tajik and Russian, plus creole Portuguese in Macao);
9. Korean; and
10. Austronesian (the Gaoshan nationality, a dozen languages indigenous to Taiwan, with few speakers on the mainland).

The historical linguistic connection between Chinese and the Tibeto-Burman languages is fully established (Benedict, 1972; Coblin, 1986; Thurgood and LaPolla, 2003). The relationships within the Tibeto-Burman language family are also widely researched (Bradley, 1979; Matisoff, 2003). Chinese scholars suggest a close link of Sino-Tibetan languages with the Tai-Kadai languages, but this has been disproven by Benedict (1975), who instead linked the Tai-Kadai, Austronesian, and Miao-Yao families. The 'Altaic hypothesis' links Turkic, Mongol, Manchu-Tungus, and Japanese-Korean, although this is dubious. Marginal to China are the Mon-Khmer or Austro-Asiatic groups in the southwest and the Indo-European groups. Conversely, Japan, Korea, and Vietnam were long under the cultural influence of China.

The Chinese Language

There is a long tradition of philological and epigraphic work on Chinese, notably Karlgren (1957); the best summary is Sagart (1999). There are also many excellent studies of Chinese syntax, especially Mandarin, notably Li and Thompson (1981). Chinese linguists have worked particularly on phonology and lexicon.

China is known in Chinese as *Zhongguo* 'middle nation,' and indeed the cultural influence of China and the Chinese on all its neighbors has been profound. Chinese has been the dominant language of China for millennia, but many other languages are spoken in China. The languages of China fall into ten main groups:

1. Sino-Tibetan, including Sinitic (Han Chinese, the majority nationality) and Tibeto-Burman (17 nationalities, more than 100 languages) throughout the country;
2. Manchu-Tungus (Manchu, Xibo, Ewenk, Oroqen and Hezhe nationalities, seven languages) mainly in the northeast;
3. Mongol in the north central region (5.5 nationalities, including half of the Yugur, seven languages);
4. Turkic (6.5 nationalities and seven languages, with the other half of the Yugur);
5. Austro-Asiatic or Mon-Khmer in the far southwest (Wa, Bulang, De'ang, and Jing nationalities, plus some small unclassified groups, more than 12 languages);
6. Tai-Kadai in the southwest (nine nationalities, more than 20 languages);
7. Miao-Yao in the southwest central area (Miao, Yao, and She nationalities, 27 languages);
8. Indo-European (two nationalities, Tajik and Russian, plus creole Portuguese in Macao);
9. Korean; and
10. Austronesian (the Gaoshan nationality, a dozen languages indigenous to Taiwan, with few speakers on the mainland).

The historical linguistic connection between Chinese and the Tibeto-Burman languages is fully established (Benedict, 1972; Coblin, 1986; Thurgood and LaPolla, 2003). The relationships within the Tibeto-Burman language family are also widely researched (Bradley, 1979; Matisoff, 2003). Chinese scholars suggest a close link of Sino-Tibetan languages with the Tai-Kadai languages, but this has been disproven by Benedict (1975), who instead linked the Tai-Kadai, Austronesian, and Miao-Yao families. The 'Altaic hypothesis' links Turkic, Mongol, Manchu-Tungus, and Japanese-Korean, although this is dubious. Marginal to China are the Mon-Khmer or Austro-Asiatic groups in the southwest and the Indo-European groups. Conversely, Japan, Korea, and Vietnam were long under the cultural influence of China.

The Chinese Language

There is a long tradition of philological and epigraphic work on Chinese, notably Karlgren (1957); the best summary is Sagart (1999). There are also many excellent studies of Chinese syntax, especially Mandarin, notably Li and Thompson (1981). Chinese linguists have worked particularly on phonology and lexicon.

Outsider linguists often say that the Han Chinese speak seven distinct, mutually unintelligible languages:

- Beifanghua ('northern speech') (known as Mandarin in English) in the north and west;
- Wu around Shanghai;
- Min in and around Fujian and in Taiwan;
- Yue (known as Cantonese in English, from the name of Guangdong Province) around Hong Kong, Guangzhou city, and most of Guangdong;
- Hakka (also known as Gejia in Mandarin), widely scattered across the southeast; and
- The inland varieties Gan and Xiang.

Some scholars further subdivide Mandarin, and there may be some additional varieties of Chinese, such as Waxianghua in southwestern Hunan. From a Chinese perspective, these varieties are all historically part of the Han Chinese majority group, all share the same *zhongwen* 'middle writing' Chinese character writing system, and all speak some *fangyan* of the Han Chinese *yuyan*. *Fangyan* is usually translated as 'dialect' and *yuyan* as 'language', but their meanings are broader. Among the minority languages, many historically related and structurally similar mutually unintelligible speech varieties are also classified together.

Norman (1988) and Ramsey (1987) provide an excellent introduction to the differences between the various varieties of Han Chinese. These are particularly great in phonology and lexicon, with lesser morphosyntactic differences. Many scholars suggest that the Han Chinese varieties diverged in the 7th century A.D., but some separated considerably earlier.

The non-Mandarin speech varieties of many cities also continue to be written, especially for local opera and folklore; additional local characters are used for words that do not exist in Mandarin. Lexically, every non-Mandarin speech variety is full of borrowings from other varieties, especially from Mandarin, including several strata from Mandarin of different periods.

Sociolinguistics of Chinese

In the long history of China, diglossia developed gradually, with Confucian and other texts from the mid-first millennium B.C. remaining the standard for official literary use up to 1911; this came to be called *wenyan* 'writing sound'. Alongside this, popular spoken-language literature, known as *baihua* 'white speech', came into use over the last millennium. During most dynasties, the spoken language of daily administration has been a Mandarin dialect, and this came to be known as *guanhua* 'official speech'; however, other varieties of Chinese were used locally. During the Republic period (1911–1949), the Mandarin of Beijing was standardized and made the official written language as well, under the name *guoyu* 'nation language'. In the 1950s, Beijing Mandarin was again codified, and in 1958 it was made the national language, under the name *putonghua* 'common speech'. The lexical differences between *guoyu,* which is still the official language in Taiwan, and *putonghua,* which has constitutional status as the national language in the People's Republic of China (PRC), are substantial and growing. The PRC has made major educational achievements in spreading putonghua alongside other spoken varieties of Chinese and minority languages and literacy in Chinese characters. There is also a standard romanization for putonghua called *pinyin* 'phonetic writing', introduced in 1958. Pinyin was originally intended to replace characters, but this plan was soon dropped.

The sociolinguistic situation in Hong Kong is interesting. Cantonese is diglossic, with a literary and formal spoken high version that is quite different from the spoken low version. Since mid-1997 Cantonese, Mandarin, and English have had co-official status. Knowledge and use of Mandarin has spread widely since the late 1980s, but is still far behind most of China; traditional rather than simplified characters and Cantonese continue in general use.

Writing Systems

The Chinese character writing system, with nearly four millennia of history, is a strong unifying characteristic for Han Chinese of all spoken varieties. Because it is logographic, sound change does not require orthographic reform. However, in 1958 a major reform was introduced in China; this simplified more than 36% of the frequently used characters and restricted the use of all but 6196 characters (Bradley, 1991: 310). The traditional full-form characters are still used in Hong Kong and Taiwan and by many overseas Chinese, but simplified characters are now used in Singapore and Malaysia. Conversely, full-form characters have been returning to use in China since the 1990s, especially for contacts with overseas Chinese, study of ancient literature, and greater status and formality.

Some of the other languages of China also have logographic scripts; some are directly derived from traditional Chinese characters, with additions following the same principle of combining a radical (semantic element) plus a phonetic. These include the Zhuang orthography as well as the better-known Japanese *kanji* 'Chinese characters', Vietnamese *chu nôm*, pre-hangul Korean, and so on. Distinct logographic

systems include Naxi and four separate traditions of Yi.

Mongol (Peripheral Mongolian) and Manchu were long written with Sogdian scripts. Tibetan is written with an Indic-derived script; one Mongol emperor tried unsuccessfully to replace Chinese characters with a modified Tibetan script in 1269. Turkic and other language groups in western China switched from Sogdian to Arabic scripts in the 13th century A.D. Some minority languages had scripts (mainly romanizations) devised by Christian missionaries. The missionary Samuel Pollard used roman letters, letters from Pitman shorthand, and invented letters in his script, mainly used for Miao and some Yi languages. In Pollard scripts, consonants are large, vowels are small, and the position to the vowel relative to the consonant indicates the tone: above for high etc.

From the 1950s onwards, new romanizations for many minority languages were produced following the principles of pinyin. Some were created to replace existing orthographies (for Lisu, Lahu, Miao, Wa, and other Christian scripts, along with various Arabic scripts); others were created for then-unwritten languages. When Russian linguists were active in China, some Cyrillic letters were used; but after 1958 most were removed. Since the 1980s, some groups have gone back to their pre-1950 scripts, especially Arabic in Xinjiang and Christian romanizations and others in the southwest (Lisu, Miao, etc.). Conversely, the Yao pinyin-based script of the 1950s became the basis of a unified Yao orthography also used by Yao outside China.

Minority Languages

The classification of non-Han ethnic groups was a gradual process. Four historically important groups – the Mongols, Manchu, Tibetans, and Hui – were recognized during the Republic period (1911–1949); the PRC flag has one large star representing the Han majority and four smaller stars representing these four groups. During the 1950s, a further fifty national minorities were recognized, and in 1978 the Jinuo nationality was added. Like the Han Chinese majority, some of the national minorities are linguistically highly composite; the Yi nationality, for example, includes six language clusters and many more distinct languages. In some cases, the ethnic classification links unrelated or distantly related languages. For example, the Lajia of eastern Guangxi, who speak a Tai-Kadai language (Lakkia), are included in the Yao nationality; the Yao of Hainan are included in the Miao nationality; and the Nu nationality includes speakers of four languages – two of which, Raorou (Zauzou) and Nusu, are Burmese-Yi languages, one of which, Dulong (Drung), is also the language of the Dulong nationality, and the last of which, Anong (Nung), is related to Dulong and to Rawang in Burma (Myanmar). For maps and linguistic classification, see Wurm *et al.* (1987/1991) or Moseley and Asher (1994).

Ramsey (1987) and Bradley (1994, 2001) have discussed language policy for minorities. Briefly, each recognized nationality has the constitutional right (but not the obligation) to maintain and develop its language and culture, and for each nationality one or more 'standard' varieties has been selected and codified. The overall policy is transitional bilingual education in the first few years of primary school. In some minority autonomous areas, local government has decided to maintain their language even up to university level, but this is the exception. With the transition to a market economy, education in and use of minority languages is decreasing.

Table 1 gives census population figures for all recognized groups in China. The large minority population increases between 1982 and 2000 reflect minority re-identification of Sinicized people who do not speak their traditional minority languages. The Unclassified category includes many very small groups who have not been recognized as separate national minorities and has gradually decreased as some such groups have been assigned to existing nationalities. For example, the 40 000 Kucong of south central Yunnan, who speak a language quite closely related to Lahu, were amalgamated into the Lahu nationality in 1987; and the 5000 Laomian in southwestern Yunnan, whose language is only distantly related to Lahu but who live in Lahu areas and are mostly bilingual in Lahu, were amalgamated into the Lahu nationality in 1990.

The Hui nationality is mainly composed of Muslim speakers of local varieties of Chinese and is usually said not to have a language. However, there is one group of Hui in Gansu who speak a distinctive variety of verb-final Chinese, presumably as a result of influence from languages of the area. Another group of Hui in Tongren County, the Qinghai Province, are locally called Kangjia and speak a Mongol language closely related to Bao'an (Bonan). A third group of Hui in southern Hainan speak a Chamic Austronesian language, Tsat.

The Mongol nationality also shows how ethnic identity and language are not necessarily linked. This group includes the Mongols, whose language is similar to the speech of Mongolia and of the Buriats in Russia. It also includes several southwestern groups who claim descent from Mongol armies sent to China during the Yuan (Mongol) Dynasty. The 'Mongols' of southwestern Sichuan are in fact Moso, speakers of a

language classified as eastern Naxi, whose speakers are included in the Naxi nationality in adjacent Yunnan. The 'Mongols' of Tonghai County in south central Yunnan speak a Yi language. The Yugur nationality is another composite group; about half speak a Turkic language and half speak a Mongolic language.

Contact Languages

Since the 1950s putonghua has increasingly become the lingua franca throughout China. It is used as a second Mandarin variety by those whose first speech variety is another kind of Mandarin, as a second Chinese variety by 300 million whose first speech variety is a non-Mandarin variety, and by an increasing proportion of minorities. The trend is for the urbanized or educated minority group members not to speak their traditional languages at all.

Several contact languages have developed in China. One such language is spoken in Wutun and two nearby villages in northeastern Qinghai; it is structurally mainly Mongol, with extensive postpositional agglutinative morphology. However, the speakers follow Tibetan Buddhism (as most Mongols did from the Yuan Dynasty onward) and have long been in close contact with Tibetans and Han Chinese; therefore, the speech of Wutun contains a very large proportion of Tibetan and Chinese lexicon and also shows some influence from the syntactic structures of Tibetan and Chinese. Another is the Portuguese creole of Macao, now moribund; it has extensive Cantonese lexicon, in addition to the various strata of lexicon from previous contact in Malacca (now in Malaysia) and India.

Language Endangerment

Several large nationalities are rapidly losing their languages. This includes the very large Manchu nationality, former rulers of the Jin and Qing dynasties, with about 20 very old speakers left in remote areas. In the southeast, the language of the She nationality in Guangdong Province now has fewer than a thousand speakers, or less than 0.1% of this group. The Gelao nationality, mainly in Guizhou, has fewer than 1% speaking any of the various Gelao languages. Similarly, less than 1% of the Tujia nationality in Hunan and nearby speak either of the two traditional Tujia languages (Northern and Southern Tujia). The Xixia language, formerly spoken in what is now Ningxia and Gansu, has been extinct for over 700 years; many other languages have doubtless disappeared, their descendants now speaking Chinese.

Many of the smaller groups included within composite national minorities speak endangered languages. Bradley (forthcoming) lists 90, including 49 Tibeto-Burman, 16 Tai-Kadai, 7 Miao-Yao, 7 Tungusic, 6 Mon-Khmer, two Turkic, two Mongol, and one Indo-European creole. One example is the Sanie just west of Kunming in Yunnan (Bradley, 2005; Bradley and Bradley, 2002; Bradley *et al.*, 1999). In 76 villages there are 17 320 Sanie, classified as Yi nationality; some of the Han Chinese population of Kunming doubtless also have unremembered Sanie ancestry. All 8000 remaining speakers are bilingual in Yunnanese Mandarin, and most of these are adults.

The long-term prognosis for many non-Han languages of China is bleak. This is especially so for those that are spoken only in less remote areas of China, are not designated as the standard language for their nationality, and do not extend into adjacent countries where they also have official status (Mongol, Korean, Russian, Vietnamese, Tajik, Kazakh, Kirghiz, and Northern Uzbek).

Chinese Religion

Scholars have devised several models to describe the Chinese religious situation at various periods of history. One model that well describes the situation since the Song dynasty (960–1279) considers that – with the exception of religions (Islam, Christianity) that arrived in China from the outside and could not become fully integrated because of exclusive claims of truth – all religious practices, beliefs, and organizations in China belong to a single system, best called Chinese religion. This organic, pluralist, and nonhierarchical system integrates traditions of individual salvation (meditation and bodily techniques, morality, and spirit-possession techniques, including spirit writing), communal celebration (cults of local saints and ancestors), and death rituals together with three institutionalized religions, Buddhism, Taoism, and Confucianism. The sectarian tradition that formed around the 15th century has sometimes been described as China's fourth religion; it has distinctive scriptures and a theology of its own, but is actually well integrated socially into the larger religious system.

The basic principles of Chinese religion were already attested in late antiquity (before the advent of the Qin empire in 221 B.C.E.). They include a cosmology describing an organic universe without either notions of separate matter and spirit or an external creative force that evolves continuously according to objective rules explained by symbolical models (*yin* and *yang*, five phases, trigrams...); a sacrificial liturgy for ancestors and local territorial gods as well as dead heroes and related purification rules (*zhaijie*); practice of spirit possession; and exorcisms to cure illnesses and improper possessions. During the Han dynasty (206 B.C.E.–220 C.E.), Confucianism, the heir of the sacrificial religion of the nobility, was constituted as state religion; Taoism was fully formed as a religion with a distinctive theology, liturgy, clergy, and churchlike organization; and Buddhism began to arrive from Central Asia.

During the medieval and Tang periods (3rd to 9th centuries), Taoism, Buddhism, and Confucianism alternated competition and cooperation before the affirmation of their coexistence and equal orthodoxy was firmly established as an imperial doctrine. All three institutionalized religions attempted to take control of numerous local cults and their spirit mediums with limited success. During the Song period, within the context of a strong demographic and economic expansion, local communities constituted around the cults of their saints, as well as corporate lineages devoted to the cult of their ancestors, emerged as the most common and powerful religious institutions and ushered in a tremendous rise of vernacular religious arts (notably opera and other performing arts in the framework of temple festivals) and techniques (spirit writing, which allows an unmediated direct access to deities and saints). Meanwhile, the clerical institutions of the three religions remained extremely prestigious and respected as they provided scriptural (elaborating theological justifications for local cults) and liturgical services to such local, lay religious communities. This pluralist system remained in place until a sudden shift in religious policies during the 20th century, inspired by the introduction of Western notions, restrained the extent of officially tolerated religious activities. The Republican (1912–) and Communist (1949–) regimes distinguished five authorized although controlled religions (Buddhism, Taoism, Islam, Catholicism, and Protestantism) but actively suppressed superstitions, notably local cults (the Nationalist government in Taiwan has strongly liberalized its stance since the 1970s). This suppression, though, has been much less effective than expected, as the strong renewal throughout the Chinese world, notably on the mainland since the 1980s, shows.

The three institutionalized religions are each precisely defined by a distinctive clergy, a canon (scriptures, which define orthodoxy), a liturgy, and training centers (monasteries, academies, where the canon is kept and the clergy is trained and ordained). The institutions defined by these four characteristics can be properly named Buddhism, Taoism, and Confucianism. They do not exist in isolation but serve Chinese religion as a whole. This whole is not syncretism as it is too often described; the three institutionalized religions are expected to coexist but not mingle, and people do not confuse them. It is an organic, pluralistic religious system. Also, it might prove very useful to dispense totally with the much-abused notion of 'popular religion' or 'folk religion' and indeed with the very word *popular*. The many independent communities that form the social structure of Chinese religion choose within the shared repertoire of beliefs and practices and the services offered by the three religions those that give them relevant meaning, and their choices hinge on socioeconomic, ideological, and theological considerations much more complex than an elite/popular dichotomy can suggest.

The role of Confucianism, Buddhism, and Taoism within Chinese religion then is not to exist as exclusive

institutions providing their members a way to salvation, as the 19th-century Western concept of religion would imply, but rather to transmit their tradition of practice and make it available to all, either as individual spiritual techniques or liturgical services to entire communities. In late imperial times and well into the 20th century, only clerics and a small number of retired laymen (*jushi*) would declare themselves Buddhist or Taoist, but very few Chinese indeed would never engage in Buddhist or Taoist practices. The wide acceptance and official status of the doctrine of the three religions' coexistence made them complementary. The services offered by the three religions and their clerics were comparable in many respects, sometimes causing collaboration and/or competition, while each of the three also provided unique services.

The Three Religions' Approach to Languages and Texts

The birth of Chinese writing is closely associated with religious practices, as the earliest available instances of Chinese writing are divination records, the *jiagu wen*. These texts were written on tortoise breastplates and mammal bones that had been heated after a question was asked of ancestors or other gods, and the answer was read in cracks caused by the heating: both question and answer were subsequently noted on the used breastplate or bone and kept in royal archives. Written language served to keep track of divinations, then, but was not instrumental in the divination process itself.

Among the various institutionalized religions that developed in China, whether indigenous (Confucianism, Taoism) or imported (Buddhism) (*see* **Buddhism, Tibetan**), we might oppose those essentially based on oral teaching and liturgy, that is, Confucianism and Buddhism, and Taoism, which is fundamentally predicated on written texts. This might come as a surprise since both Confucianism and Buddhism are well known for their extensive canons, exegetical tradition, and high valuation of reading and study. However, both these religions describe their own history as initially characterized by oral transmission before reaching a stage at which writing texts became necessary, and only then as a way to safeguard the tradition. Confucius himself claimed to have merely written the texts that he, like any gentleman, had learned as a child. These texts, which became the scriptures/classics (*jing*), that is, authoritative standards for orthodoxy within Confucianism, are fundamentally linked to liturgy. They include the Book of Odes (*Shijing*), essentially odes and hymns to be sung during rituals; the Book of Documents (*Shujing*) recording the grand rituals performed by past kings; the *Yijing*, a divination manual; and liturgical manuals.

A broadly similar process, but under very different circumstances in India, occurred in Buddhism, in which the teachings of the Buddha were reportedly transmitted orally and only noted down during a council when various versions began to diverge too widely. It was only much later, within the early so-called Mahayana (great vehicle) networks, that a devotion to texts as objects formed, linked to a divinization of texts themselves identified as Buddhas and also to specific revelation techniques.

On the other hand, Taoism very early developed a specific theology of writing, whereby written characters in their primordial form (of which the commonly used characters were merely imitations) are considered fundamental elements in the structure of the universe, embodying primordial truths, hence the name *zhenwen* (transcendent writs) for scripts used in the construction of Taoist ritual altars. Similarly, talismans (*fu*) are construed the true names of various cosmic forces, and the proper writing of talismans gives the priest command on such forces. Talismans and transcendent writs are not pronounced but only written. Thus, in contrast to Confucian and Buddhist liturgies in which the crucial act is the proper recitation of texts and hymns, Taoist liturgy hinges on written communication with forces of the Dao. The priest, after purification, writes the various memoirs, requests, and other communications according to precise forms, rules, and models (writing mistakes are punished by the gods); burns them (fire is the main channel of communication between this and the other world); and silently in meditation raises to submit the requests himself in audience with Heaven. This liturgy of the sacrifice of scriptures (which within Taoism replaces the sacrifice of meats of common religion, see Schipper, 1974) has been well attested since the 2nd century C.E. and remains central to Taoist liturgy in the 21st century.

Devotional practices linked to written characters found their first known expression in Taoist community rules (the 'Hundred eighty rules of the Supreme lord', probably 2nd or 3rd century C.E.) and much later developed into a practice known as *xizi*, 'Care for written characters', embedded into common religious ethics of the early modern period (16th to 19th centuries). *Xizi* adepts consider throwing away a paper or other material with any written characters on it (not only scriptures, but any text) as a sin; they treat all such material with care, pick up those discarded by others, and regularly burn them in a clean furnace before bringing the ashes to the sea or a river.

Buddhist influence, notably through the Lingbao revelations (early 5th century C.E.), has caused Taoism

to adopt the oral recitation of scriptures (different modes of chanting exist according to the exact nature of the text, see Boltz, 1996) as a part of rituals and to adopt notions (of Indian origin) of sacred and efficacious sounds proper to the Buddhist tradition. The Buddhist tantric tradition of *dharani*, texts whose recitation provoke a spiritual effect, was also adopted in China well beyond Buddhist circles, and *dharani* texts are found engraved on many supports and are recited in case of danger (Strickmann, 1996).

As a consequence of the adoption of Buddhist notions of efficacious sounds, Buddhist and Taoist clerics have to pronounce (in some cases orally, in others silently) incantations/spells, *zhou* (see Sawada, 1984), that ensure purity and avoid demonic contamination in many precise circumstances (eating, urinating, getting to sleep). Moreover, Chinese religious practice, including the sectarian tradition, values mantras, that is, secretly transmitted efficacious words, either in proper Chinese or in (pseudo-)Sanskrit (*see* **Sanskrit**). On the other hand, the Taoist focus on the written word has not diminished because of Buddhist influence, and Chinese Buddhism had even adopted the Taoist practice of written communication with the otherworld. Large Buddhist rituals since at least the Song period have also included sending written petitions to the Buddhas. Writing and speaking are then two distinct, parallel modes of communication with the divine, the former more Taoist oriented and the latter more Buddhist and Confucian oriented, although all traditions and communities use both media. Ordinary devotees address the deities they pray to either orally in the vernacular (no specific language of prayer has developed) or, with the help of a clerical specialist, by writing and burning a formal request (*shu*).

Scriptures and Revelations

The language of the Confucian and Taoist scriptures is not fundamentally different from that of other contemporary texts. Confucian scriptures were used in educating children (who learned them by rote) and formed the curriculum of state and private schools that developed gradually and, notably under the Song, in relation to state civil service examinations. The style of these scriptures was thus widely imitated, and citations are found throughout any oral or written discourse to the present day. Taoist scriptures, many of which were transmitted only to initiates, did not enjoy such a status as models of writing and speech, yet also exerted a deep influence on poetry, notably the Shangqing texts (revealed during the late 4th century B.C.E.), whose rich and often arduous flowery metaphors and mystic vocabulary informed later secular poetry. Aesthetic judgments on poetic and calligraphy style and doctrinal contents are deeply interconnected in the transmission and diffusion of all Chinese religious texts.

The status of Buddhist scriptures is different because these had to be translated from very different languages, most of them Indo-European (*see*). Translation strategies varied, from using the existing Taoist lexicon (which facilitated adoption, but caused confusions), to transliterating original words, to eventually creating, mostly from existing Chinese words, a new Chinese Buddhist vocabulary (Zürcher, 1991). Part of this vocabulary, including a few transliterations from Sanskrit and other Indo-European languages, has found its way into everyday language. The translation of Buddhist texts was a huge enterprise lasting from the 2nd to the 13th centuries, with the imperial state and rich patrons sponsoring whole translating institutes where native speakers of Indian or Central Asian languages and Chinese monks collaborated to produce word-for-word translations and then readable final texts. Major texts were translated several times by different teams, and the best, most readable versions eclipsed others. Incidentally, in the process of making technical Buddhist dictionaries and transliterating names and words, Chinese scholars developed ways to classify syllables according to initials and finals. At the same time as thousands of Buddhist texts were translated, others, the apocrypha, were written in Chinese while pretending to be translations, and a good deal of the scholastic activity of the Buddhist establishment consisted in compiling canons and sorting apocrypha from true scriptures according to philological as well as theological criteria. The history of translation of Islamic and Christian texts into Chinese, at later periods, bears comparison with the great Buddhist translation enterprise, although the more limited impact of these exclusive religions did not allow new words coined by translators to become everyday vocabulary.

While the Buddhist and Confucian canons were basically closed during the Song period, scriptures of Taoism, local cults, and sectarian traditions continued to appear in large numbers. One major feature of Chinese religion is the openness of revelation. Spirit possession is extremely common, and it is widely accepted that although certain forms of possession by certain spirits are dangerous or not desirable, possession is an authentic means of communication with deities and therefore of accessing truth and obtaining grace. Official religion during antiquity institutionalized possession, but this was no longer the case for Confucianism after the Han or for Buddhism. On the other hand, possession continues to this day to be practiced within the confines of local cults,

devotional groups, and sectarian communities; spirit mediums are not organized as a clergy but are trained by Taoists and work for local communities. Temple spirit mediums are usually regarded with disdain and sometimes hostility by clerics, but play a crucial role throughout China in answering personal queries (difficult choices, righting wrongs) and healing illnesses. When possessed, they may write talismans to help, protect, or cure the patient, but also often act as oracles, speaking with the voice of the god to answer the question asked. The spirit mediums working for spirit-writing groups are different, as they are often considered to have a higher status. When possessed, they hold a forked object, usually made of wood, over a tray of sand, ashes, or just a table and write characters that are then interpreted and noted by an assistant. Books revealed by such means are extremely numerous, edited, printed, and freely distributed (as a pious act) by the groups who received them. They include morality books, *shanshu*, where deities lay out the common ethics of Chinese religion and tell tales of retribution for good or evil acts (on the language aspects of *shanshu*, see Bell, 1996); immortality techniques manuals, where immortals guide directly their adepts in their self-cultivation quest; medicinal recipes; and poetry and other narratives. Such books have been produced by the thousands since the Song, with a sharp increase around the 17th century.

Classical and Vernacular Language in Religious Practice

In China, as in many other cultures, the use of texts and language style differentiates the religious practice of various social classes and groups. As a general rule, an explicit contrast opposes the clergies (Buddhist, Taoist, Confucian), that is, specialists sharing a nationwide training and ordination system and practicing a (supposedly unified) liturgy, with the same texts, music, and chanting/reciting techniques throughout the country, to vernacular specialists totally embedded in local village culture and not related to larger clerical institutions. The former speak (during the course of the ritual) national, classical language, whereas the latter only use the vernacular local dialect (*see* **Chinese**). Such an opposition, best known through the Taoist case where specialists are divided into classical-speaking and vernacular-speaking priests (see notably Schipper, 1985), is similarly observed in the Buddhist and Confucian contexts. It should be emphasized that the classical/vernacular dichotomy is both real in the sense that it is an explicit category for both specialists and laypeople (it is crucial in this context that people do not understand what priests say when speaking in classical language) and an ideological construct hiding much more complex realities. First, the classical language used, supposedly unique throughout the Chinese world, actually varies very much from one region to the next and is often a classical/archaic form of the local language, rather than a language understandable in other parts of China.

Second, rituals actually mix classical and vernacular language; Buddhist and Taoist rituals are composed of many different rites, some very solemn with hymns that have not changed for centuries and some in which improvisation is possible, and the style is much closer to spoken language. Clerics also frequently sing ballads or tell devotional stories in the vernacular, fully understood by the audience. Largely, the same rhetorical dialectics and complementarity between the more prestigious classical and the more vulgar vernacular can be observed in the opera. Chinese opera, which formed under the Song (on the basis of more ancient and not well known antecedents), is intimately linked to Chinese religion and local cults, since temple festivals were the major venue for opera shows. Large temple festivals included both clerical (Buddhist, Taoist, Confucian) rituals within the temple and opera shows outside, both being offered to the local gods. Many opera plays have religious themes (although there is no distinction between profane/sacred themes), and some performing arts have a direct ritual efficacy, such as exorcist plays or puppet shows. Opera also mixed songs in classical language with more vernacular dialogues.

Preaching

Even though the classical/vernacular dialectics valorize the former, it would be wrong to think that vernacular language was universally considered a debased medium for communication with deities or transmitting religious truths in Chinese religious circles throughout history. First, the Song period witnessed a rise, which has not abated since, of the genre of recorded conversations, *yulu*, of spiritual masters, Confucian, Buddhist, and Taoist. *Yulu* are supposed to be verbatim records of question-and-answer exchanges between a master and his/her disciples as actually spoken, that is, in the vernacular. Some of them have actually been edited and cannot truly reflect oral usage, yet such texts are among our best witnesses of spoken Chinese language for the early modern period. The valorization of vernacular language in such texts is linked to a spiritual movement to enhance the living master, his/her actions, and everyday words, rather than the scriptures, as the main guide to truth and transcendence: such

ideas were formulated by Quanzhen Taoism, Neo-Confucianism, and Chan Buddhism, the latter having expressed the most radical statements to this effect, with a (rhetorical) rejection of scriptures as useless and a glorification of 'teaching without words' (Gardner, 1991; Berling, 1987). The late Ming (16th and early 17th centuries) move to use vernacular language in literature (notably novels) was also a religious movement with similar motivations, aiming at retrieving the language Confucius spoke.

A second reason why some religious specialists strove to use the vernacular both in print and in speech was the need to preach. Because the three religions do not have exclusive lay organizations and share the status of orthodox teachings, they do not much proselytize. Clerics and activists, however, have been active throughout history in spreading their message in both print and speech. Late imperial Confucian activists wrote manuals aimed at helping those who had, as the law mandated, to recite an imperially written text on morality (the 'Sacred edicts', *shengyu*) to villagers twice a month. As the sacred edicts in terse written classical style were hardly intelligible when recited aloud, these activists wrote texts in various shades of vernacular aimed at explaining them and providing simple examples (Mair, 1985). Buddhist and Taoist preaching (*see* **Preaching**) was usually somewhat different, being less-tersely didactic and relying more on performing arts techniques. Medieval (5th to 10th centuries C.E.) manuscripts found in Dunhuang include such Buddhist preaching texts (*bianwen*) alternating vernacular speech, rhymed songs, and large images to be shown to the audience. Taoists also developed songs (notably *daoqing*, 'Taoist feelings' ballads) to be sung by clerics and/or professional performers during festivals, promising salvation and appealing to conversion. Devotional literature, telling the stories of the saints and the retribution of evil in the prosimetric style alternating prose and rhymed songs and known as *baojuan*, has been extremely widespread since the 16th century. *Baojuan* performers are invited during temple festivals or in the houses of the large families to recite their texts, a meritorious, pious, and at the same time enjoyable performance that can last for nights on end.

China: Scripts, Non-Chinese

M Bender, The Ohio State University, Columbus, OH, USA

© 2006 Elsevier Ltd. All rights reserved.

Soon after 1949, influenced by policies already instituted in the Soviet Union, the new government of the People's Republic of China decided to promote the recognition of ethnic minority peoples on a scale unprecedented in Chinese history. Groups with fully functional, widely used traditional scripts include the Uygur, Kazak, Mongols, Koreans, and Tibetans (Zhou, 2003: 280). The Yi, Naxi, and Dai had writing systems used only by shamans, priests, or monks. In the pre-1949 era, several scripts were created by Western missionaries (such as Samuel Pollard, Alfred Lietard, and Pere Paul Vial) for some divisions of the Miao, Jingpo, Lisu, Hani, Lahu, and Wa (Va) and the Yi subgroup known as Sani. Other scripts used by the Zhuang, Shui, and Dong were based on vernacular usages of Chinese characters and had very limited implementation. Miao epic poems from Guizhou Province mention an ancient, but lost, script. An absolete form of phonetic script different in form from both Chinese and Yi scripts (see below) and consisting of approximately 180 graphs dates to the Qing dynasty (1644–1911). A traditional 'women's script' (*nushu*) of unknown origin (some have suggested a minority link) was in recent use in Jingyong County, Hunan Province, for writing letters and stories in verse.

One goal of the early era of minority recognition was the creation of written scripts for those groups that did not have a tradition of writing. By the early 1950s, Chinese linguists, often working with local representatives, had begun to devise scripts for a number of the groups, especially those living in the border areas of the southwest. Initially, Cyrillic and roman alphabets were utilized in creating new scripts. In some cases, the International Phonetic Alphabet (IPA) was also used, sometimes in combination with the other systems. Ultimately, roman letters (sometimes with IPA symbols) prevailed in the official scripts, which numbered approximately 13. The trend toward roman letters was strongly influenced by the adoption of the Pinyin romanization system, developed between 1956 and 1958, for writing the sounds of Standard Chinese. Over the ensuing years, script creation was affected by policy revisions, national and local budget allocations, the rate of publication and distribution of script materials, and the degree and effectiveness of local implementation and use. In a few cases, the created scripts crossed borders, as in the case of the Jingpho (Jingpo) script used in Yunnan and contiguous ethnic areas in Myanmar.

Among the first languages targeted for the creation of a new script was Northern Zhuang (Zhuang). China's largest ethnic minority group, the Zhuang, number approximately 15 million and live in the Guangxi Zhuang Autonomous Region and surrounding areas in the southwest. A major challenge was finding a system that could represent the sounds of the various Zhuang dialects, some of which are mutually unintelligible. The key question was which dialect would be the basis for the writing system – an issue in the creation of many of the other minority scripts. At the urging of a Russian specialist, the Wuming dialect was chosen as a standard. A romanized script was first proposed in the early 1950s, but again on Soviet advice, a system combining roman letters, Cyrillic letters, and certain IPA symbols was adopted in the mid-1950s. This script was put to limited use until it was displaced by an all-roman system in 1982. As with several other southern minority scripts, consonant letters placed at the end of a morpheme were used to represent the linguistic tones. Examples of the Pinyin-based script are as follows: *vunz* ('person') employing the second tone (55), *menh* ('slow') employing tone six (33), and *laeuj ndok guk* ('tiger bone wine') employing an alternate usage of the third tone (55) and tone seven (35). Dictionaries, school texts, signs on government offices, and folk literature utilizing the script appeared throughout the 1980s, though Chinese continues to be the primary script for most Zhuang speakers.

By the mid-1950s, Russian linguists were also advising Chinese scholars either to adapt Cyrillic systems already developed in the Soviet Union for scripts for small, seminomadic transborder groups such as the Ewenki and Oroqen, or to create new Cyrillic-based scripts for larger or more sedentary groups of Mongolian-related speakers in northern and northeastern China. One case was Daur, spoken by approximately 100 000 people in eastern Inner Mongolia and Heilongjiang Province (with several thousand speakers in Xinjiang, as well). Traditionally, the Daur have no written scripts of their own. A Cyrillic-based script was created. One concern was the representation of vowel chronemes, which was solved by using double roman letters (such as the Russian 'a' for the IPA 'a', represented as 'aa') (Zhou, 2003: 179–180). This script, however, was never widely implemented. By 1980, a new romanized Daur script was in limited use that included experiments with the script in schools, the publishing of a Daur/Chinese dictionary, and the publication of some folk songs

and stories. Some features of the earlier Cyrillic-based script were carried over into the Pinyin-based romanization, including the representation of chronemes, as exemplified by the words *baatur* ('hero'), *maamaa* (child's term for 'horse'), and *taawudaar* ('number five' in a series). Similar conventions are used in some other scripts, including a mixed IPA and Pinyin script later developed for representing Oroqen, as with *axaaj* ('elder brother') and *axaxaan* ('little brother').

The case of the Yi nationality of the Liangshan Yi Autonomous Prefecture, Sichuan, is unique in that a whole new syllabary was created out of traditional logographic and syllabic graphs. Beginning in the 1950s, a romanized script was created to write the sounds of a variety of Sichuan Yi (Northern Yi) (Bradley, 2001: 207). Three of the four tones in Shynra dialect are represented by final consonants; t (55), x (44), p (21). The mid-level tome (33) is unmarked. An example of the script from a textbook (Li and Ma, 1981: 2) is as follows:

Speaker A: **Nop jiet nyi zzyrmuo bat?**
Your home also well (particle)?
Is your homes well also?
Speaker B: **Zzyrmuo ggehni jjoddu ap jjo.**
happy healthy worries not have.
No worries, all happy and healthy

The romanized script, however, failed to gain popularity, in part because of local attachments to the native writing system (once used by approximately 2% of the population, mostly ritual specialists). In the 1970s, efforts were made to develop a syllabary based on traditional graphs. By 1980, a new syllabic script was being taught in many schools throughout the Liangshan Prefecture and neighboring Ninglang Prefecture in Northern Yunnan. The syllabic script was based on 819 traditional graphs and the Shynra dialect pronunciation (as spoken in Xide County). Newspapers, journals, textbooks, poetry collections, folklore, and other writings have been published in the script, though most modern Nuosu authors write and publish in Chinese, the medium of officialdom. Although the script was welcome in Northern Yi-speaking areas, it was inadequate to meet the needs of speakers from other dialect areas where the traditional scripts vary greatly. Thus, attempts have been made in Yunnan and Guizhou to create a 'supra-X' system based on approximately 2000 traditional characters. It has yet to be fully developed and local conventions are in use in several areas. For instance, scholars of the Sani subgroup in Yunnan have published a number of multilinear folk literature texts combining local versions of traditional Yi characters, IPA symbols to represent Yi sounds, and Chinese graphs. Another factor working against script acceptance in some areas of Yunnan and Guizhou is a decline in speakers of local Yi dialects.

Around 1905, Samuel Pollard created a nonroman alphabetic script for a Miao subgroup (Hua Miao) in eastern Yunnan. The script was modified several times in the 1950s, but is still in use in some areas today (Zhou, 2003: 317–323). By the late 1950s, Chinese linguists had devised romanized scripts for several Miao groups in Guizhou and contiguous areas. As with Yi, the varying degree of intelligibility between dialects has made it difficult for researchers to achieve the elusive goal of a universal Miao romanization system. Although written Chinese is the major script in all the Hmong-(Miao-) speaking areas, in some places the romanized Miao scripts have been implemented in limited ways. In the case of the Eastern dialect (which represents a group of three subdialects in the Eastern Guizhou province), dictionaries, grammars, and folk literature texts have appeared in bilingual editions. In a grammar designed to introduce the Eastern romanized script, eight speech tones are represented by consonants attached to each morpheme: b (33), x (55), d (24), l (22), t (44), s (23), k (53), f (21). An example of first tone usage is *dab* ('reply'), with the second tone *dax* ('come'), the third *dad* ('length'), and so forth. The work also included several long folk stories written in the script. The following sample is from *Dail Daib Pik Vongx* (*The dragon maiden*) (Wang, 1985: 224). The text was presented in a multilinear format with word-for-word Chinese (here substituted by English, followed by a translation):

nongd nangx ngax hek jud, nenx ghax dad laib khangb lol ket tob tob:
need eat meat drink wine, need then grab a calabash come shake lightly lightly:
When he needed to drink wine, he just took the calabash and shook it lightly, saying:
"lol ngax khangb! lol ngax dit ob bad daib nangx khangb!
"come meat calabash! come meat for us father–son eat!
Calabash, bring on the meat, bring on the meat for this father and son to eat!
lol jud khangb! lol jud dit ob bad daib hek khangb!"
come wine calabash! come wine for us father–son drink calabash!"
Calabash, bring on the wine! bring on the wine for this father and son to drink!"

Since 1949, revisions have been made to a number of the traditional scripts, and over a dozen official scripts (and numerous unofficial ones) have been created for various ethnic groups in China. However, social and economic pressures will be a determining factor in the continued use of the minority scripts. The needs of information technology offer new

avenues for the development and use of romanized scripts. By the late 1990s, computerized script programs had been developed for all the major traditional written scripts and several of the newer ones. For example, researchers have developed a romanized Uyghur (Uygur) script that is more compatible with on-line usage than the Arabic-based traditional script (Zhou, 2003: 138). Nevertheless, without increased promotion, it is likely that many of the newer scripts will eventually exist primarily as tools for scholars and symbolic markers of ethnicity.

The Chinese characters are a unique form of writing in the modern, integrated world. They have been the primary script across East Asia, and they have proven to be fascinating to the entire world. In China, their two major forms are those of ancient inscriptions:

1. bronze (*jīnwén* 金文)
2. oracle bone or 'OBI' (*jiǎgǔwén* 甲骨文, *qìwén* 契文)
3. seal (*zhuànwén* 篆文, *zhuànshū* 篆書, *xiǎozhuàn* 小篆)

and the newer ink-brush styles:

1. clerical (*lìshū* 隸書)
2. 'running' and 'grass' (*xíngshū* 行書, *cǎoshū* 草書)
3. modern square script (*kǎishū* 楷書)

In Chinese society today there is considerable knowledge about ancient scripts outside of the community of scholars of paleography. All known styles of Chinese script, including those recently rediscovered through archaeological excavation, are the subject of modern calligraphy practice, one of the prime vehicles of self-cultivation in Chinese traditional secular culture.

Ancient Inscribed Styles

Seal

Seal script has been used on signature seals since 'Warring States' times (475–221 B.C.E.), and was the main form used in public inscriptions in the Qín (221–206 B.C.E.) and Hàn (B.C.E. 206–221 C.E.) dynasties. The Qín standardization of the script is thought to have involved seal script, although it is less well known that Qín itself cultivated a highly conservative character structure in an effort to show that it was the worthy successor of the Zhōu. Seal script has long been used on official seals, and so is associated with political legitimacy.

The Chinese characters are a unique form of writing in the modern, integrated world. They have been the primary script across East Asia, and they have proven to be fascinating to the entire world. In China, their two major forms are those of ancient inscriptions:

1. bronze (*jīnwén* 金文)
2. oracle bone or 'OBI' (*jiǎgǔwén* 甲骨文, *qìwén* 契文)
3. seal (*zhuànwén* 篆文, *zhuànshū* 篆書, *xiǎozhuàn* 小篆)

and the newer ink-brush styles:

1. clerical (*lìshū* 隸書)
2. 'running' and 'grass' (*xíngshū* 行書, *cǎoshū* 草書)
3. modern square script (*kǎishū* 楷書)

In Chinese society today there is considerable knowledge about ancient scripts outside of the community of scholars of paleography. All known styles of Chinese script, including those recently rediscovered through archaeological excavation, are the subject of modern calligraphy practice, one of the prime vehicles of self-cultivation in Chinese traditional secular culture.

Ancient Inscribed Styles

Seal

Seal script has been used on signature seals since 'Warring States' times (475–221 B.C.E.), and was the main form used in public inscriptions in the Qín (221–206 B.C.E.) and Hàn (B.C.E. 206–221 C.E.) dynasties. The Qín standardization of the script is thought to have involved seal script, although it is less well known that Qín itself cultivated a highly conservative character structure in an effort to show that it was the worthy successor of the Zhōu. Seal script has long been used on official seals, and so is associated with political legitimacy.

Figure 1 A page from a Sòng dynasty dictionary of seal forms, with text in square script.

Seal script has been the focus of traditional paleography and graphology, because it is documented in a 1st-century dictionary, the *Shuōwén jiězì* 說文解字, the oldest native work of its kind. But seal script represents a highly evolved stage of development and is not ideal for research on the early history of Chinese writing. It is formalistic and most of its graphs are broadly isomorphic with modern square script, even though seal script differs in having lines of even weight, rounded corners, and rounded line-ends (see the example in Figure 1, from a Sòng dynasty (960–1279) compendium). Characters are written so as to conform to an invisible box and look balanced and neat.

Bronze

Some of the most structurally conservative ancient graphs tend to be those cast on early bronze vessels,

Figure 2 A Western Zhōōu bronze inscription.

which abound from the period of the Shāng (1766–1122) and Western Zhōu dynasties (1122–221). Bronze script was a monumental form; the sacrificial vessels on which it appears were often costly and had ritual functions in the ancestral temples of important families. Many short inscriptions (5–20 characters) exist, recording little more than personal names and a few formal phrases associated with the commissioning of the vessel. An example appears in Figure 2, from a Western Zhōu *guǐ* vessel. But some longer texts (as long as several hundred characters) also exist and are a major source for historical and linguistic study of this period. Their formal nature, however, must never be forgotten; this was not a medium or a context that lent itself to casual writing or to the recording of natural speech.

Bronze script graphs tend to have both regular angles and smooth curves, with lines of varying thickness and separated by irregular spaces. Their size and shape may vary considerably within a single inscription, in contrast to more standardized graphs of later periods. Texts are generally written in columns, top to bottom, continuing right to left, and, in the best inscriptions, the columns have a largely linear appearance, with the graphs about equally spaced. But graphs themselves vary a great deal in form; this is true of both the appearance of primary elements and the structure of compound graphs. Ancient bronzes have been known and handled continuously since their own time (there is a tradition in the received literature that possession of certain vessels of state betokens the possession of the throne). The collection and study of their inscriptions continues in a tradition

Figure 3 A fine oracle bone inscription on scapula.

unbroken since the Sòng dynasty, although modern archaeological finds and linguistic method have increased our knowledge incalculably in the past half century. The form shown here is taken from a modern rubbing (*tàpiàn* 拓片).

Bone

The oldest Chinese writing now known and definitively identified as writing is the oracle bone inscriptions (OBI), dating mainly from the time of the last 12 kings of the Shāng dynasty, or the period ca. mid-14th-century to 1122 B.C.E. Tortoise plastrons and carabao scapulas were used in ritual divination by or for the kings (some were also inscribed with related information), and finally they were either stored or discarded. They were first identified around the turn of the 20th century, and so their study is entirely modern. The great majority of authentic Shāng bones come from an area near Ānyáng in China's Hénán Province 河南安陽, the site of the later Shāng capital; there are also smaller finds from other parts of north China, as well as pieces dating from the early Western Zhōu. Inscriptions are generally classified into five very rough stylistic periods.

Bone and scapula are harder materials than the soft clay on which bronze inscriptions were actually prepared, and OBI are rougher in appearance, with simpler structure and lines that are more jagged (see Figure 3 for an unusually legible and large

inscription). Most OBI finds are fragmentary, and even complete texts are usually short and highly compact. For these reasons, the identification of graphs by linguistic context is often much more tentative than with bronze inscriptions.

Ink-Brush Styles

Although there is internal evidence that OBI and bronze graphs must have developed from earlier ink or painted forms, no undisputed specimens have yet been unearthed. From the 4th and 3rd centuries B.C.E., however, there are a number of examples of cursive ink writing on bamboo splints (*zhújiǎn* 竹簡) and silk (*bóshū* 帛書). Important recent finds come from sites at Bāoshān 包山 and Guōdiàn 郭店 in Húběi 湖北 Province. The texts represented in these documents tend to vary a good deal from received versions, and character structure seems to have been highly variable. The *Shuōwén* records a tradition that, in the fragmentation of 'China' prior to the Qín unification, each politically independent region developed its own style of writing. However, the variation is not simply geographical; we sometimes see the same character written quite differently even within the same document. Materials of this type were not well known in traditional times, although there is a Sòng dynasty dictionary, the *Hànjiǎn*, that contains some related forms.

Cursive brush forms tend to look much more abstract than the older bone and bronze forms. Horizontal strokes are often greatly thickened, and vertical strokes tend to trail off unless they turn and continue horizontally. A sample of a recent find at Guōdiàn appears in Figure 4.

In all brush styles, whether cursive or formal, the brush allows control of the amount of ink released, and the thickening or narrowing of lines becomes an essential part of the aesthetics of the script, in a way that was not seen in the older inscriptional styles. However, from the Hàn onward, we see inscriptions using ink-brush styles, because paper (first widely used in the Hàn) could be pasted on stone and the ink characters on it carved there. That provided a way for medieval Chinese governments to promulgate standard texts in standard script: they erected official editions of the classical texts that were a part of their intellectual basis for rule, and visitors could make rubbings and take them home for study and emulation.

Clerical

True, so-called 'clerical' script is the term applied to cursive writing from the Qín and Hàn, but these are clearly a development from Warring States cursive tradition. From the Hàn we have a number of stone steles carved from ink models. The Cáo Quán Stele

Figure 4 A fragment of Warring States brushwork.

曹全碑, dated 185 C.E. and unearthed in the 16th century, is one of the most striking examples of the style; see Figure 5. The characters are square, with many of the basic stroke types formed in a regular and distinctive way. Writers are evidently paying close attention to control of the brush-tip. Structurally, most of the characters are already very close to modern square script, in spite of stylistic differences.

'Running' and 'Grass' Styles

The 'running' (literally, 'walking') and 'grass' styles are both characterized by ellipsis of discrete structural elements and the flowing connection between various remaining lines of the graph. Grass style is the more elliptical of the two and, contrary to popular belief, is the older, dating from the Western Hàn (B.C.E. 206–8 C.E.); it was originally a cursive development of clerical script. It remains a favored style for calligraphy, and the elegance of fine specimens arouses a visceral aesthetic response in some afficionados, although the effect is often lost on viewers who cannot read Chinese, and is even baffling to them. In more extreme examples, even people who appreciate calligraphy cannot always make out every character. The (relatively moderate) work of the 14th-century Kānglǐ Zǐshān 康里子山 is shown in Figure 6. Running style is generally much more legible for the modern reader; its forms bear a much closer relationship to

Figure 5 From a Hàn stele inscription in clerical script.

modern square script, and it developed later, in the 3rd century, probably as a casual style for use in letters. A rubbing of the running script of the 8th century Lǐ Yōng 李邕 is shown in Figure 7. When the running and grass styles are compared with modern square script, the viewer becomes aware that a kind of systematic vocabulary of ellipsis is involved, and that vocabulary has been made the subject of a number of books, including one in English by Fred Fang-yü Wang (1958).

Modern Square Script and the Simplification Movement

Modern square script is the style in common use today. It seems to have developed by the 3rd century, and rapidly became standard for official writing. No later than the end of the 6th century there were dictionaries circulating that exhibited standard square script forms, no doubt for emulation. Square script does not flow; lines are discrete and generally straight. Vertical lines are supposed to go straight up and down, and horizontal lines are supposed to be almost level, or rising very slightly from left to right. Changes of line direction are clearly expressed and the narrowing and flaring of the different parts of each line are exactly prescribed. Figure 8 shows a 6th-century example from the 7th-century tomb inscription of Sū Cí 蘇慈. Even though it is obviously

Figure 6 A sample of Mongol-era 'grass' script.

not contemporary, almost all the graphs are instantly readable by any literate person today.

In the 20th century, both the Nationalist (KMT) and Communist governments of China promulgated official lists of 'simplified' characters (*jiǎntǐzì* 簡體字). Many of these graphs are essentially running script forms given a square script cast, and almost all of them have been in popular handwritten use for a very long time, at least regionally and often universally. When the Chinese civil war wound down

Figure 7 A sample of 8th-century 'running' script.

Figure 8 A sample of 7th-century square script.

to a stalemate in the 1950s, the Communist-governed mainland was promoting a simplified script as an aid to proletarian literacy and as a step toward the eventual eradication of the characters, while the KMT-governed island of Taiwan was promoting traditional script, as commonly seen in printed texts from the previous several centuries. In some cases, systematic principles are involved in how characters are simplified, but those principles were never fully implemented. For example, the traditional form 變 is officially simplified to 变, 亂 to 乱, 繭 to 茧, 歡 to 欢, 讓 to 让, and so on. The example of 變 is paralleled by 鸞, 鑾, and 欒 being simplified to 銮, 鸾, and 栾, and the case of 歡 is paralleled by 觀, 權, and 勸 being simplified to 观, 权, and 劝. But there are many other uncompleted sets: 罐, 灌, and 獾 remain unchanged in the official simplified character set, as do 瓤, 壤, and 嚷.

As of the turn of the 21st century, there has not been full popular integration of the simplified and traditional character sets in popular usage, even though the actual differences between the two are relatively superficial. Typically, a week of review is all that is needed for someone literate in one character set to master the other set. But many native speakers of Chinese still claim only to be able to read one or the other set, a declaration that the neutral observer suspects is really about political or regional allegiance rather than any intrinsic incompatibility between the two. Software developers have quietly made it possible for the two sets to be integrated in most computer applications.

As for full alphabetization and the elimination of the characters, as of this writing it remains official Communist policy, but seems to this writer unlikely ever to take place because of the dominating place of the script in Chinese identity. Enthusiasts of alphabetization include a number of prominent Western scholars. DeFrancis (1950) and Serruys (1962) give good resumes of the early history of the simplification and alphabetization movement.

Other Matters of Form and Punctuation

Form of Connected Writing

Until recent decades, Chinese has conventionally been written in straight columns, top to bottom and continuing right to left. (Bronze inscriptions occasionally run in columns from left to right, often in only one of a pair of inscriptions facing each other on the lid and body of a single vessel.) Over the course of the 20th century, it became usual to write in rows from left to right. Taiwan and conservative overseas newspapers made the switch in the late 1990s. In Taiwan and Hong Kong, much literature continues to use the traditional format. In the mainland, only scholarly works of classical literature and philology still frequently follow the traditional format.

Chinese characters in modern print are generally all the same size and occupy an (invisible) square, with the same amount of space between them. Unstressed syllables and the one important Mandarin subsyllabic morpheme (the rhotacizing 'suffix' *-r* 兒 / 儿) always take up the same amount of space as 'full' syllables.

Punctuation

Modern Chinese, since the early 20th century, has been punctuated with a set of symbols derived from Western usage: the period 。 or •, the comma, colon, semicolon, question mark, quotation marks, and exclamation point: : ; ? !. There is also a special 'half-comma' (、) used for separating items in a list (and not rendered orally as a pause, as a comma is in English). The half-comma is derived from the shape of a simple dot as conventionally written with a brush. There are traditional quotation marks 「 and 」 (or ﹁ and ﹂ in columnar format) and brackets 【 and 】 (︻ / ︼), and 〈 and 〉 (︿/﹀). It is usual for all of these punctuation marks to be given the same amount of space as a normal character, although with the advent of computers and wider exposure to other written languages, many typographical practices are in rapid coevolution. There was historically no such thing as italicization, but its availability in word processors has introduced it to the Chinese printed world since the late 1980s.

Traditional printed books usually had no punctuation, although individual readers might 'point' the text by hand, as needed, using a circle or half-comma. However, Warring States bamboo manuscripts often have 'half-comma'-like marks at the ends of what we can identify as phrases and sentences. Traditional teachers would sometimes mark alternate tonal readings of a given character by putting a dot or a small circle in one or another of its corner (so-called *quānpò* 圈破 'circling the "broken" reading'). Ancient bronze inscriptions and bamboo texts made frequent use of a 'doubling mark' (*chóngwén* 重文), which is the numeral 'two' (二) added to the bottom right corner of a character to indicate that the character was to be read twice – sometimes a series of characters could be so marked, meaning that a phrase was to be read twice. Figure 2 contains one such example in the upper left corner.

In later texts, broadly speaking from the Hàn onward, the doubling mark is given its own space as a character, fitting into its own invisible square. By the 6th century we see a more elaborate doubling mark 々 used, which survives in handwriting today.

Ligatures

Ligatures (*héwén* 合文) are very common in ancient texts. We find two common characters pressed into the space of one, often written in such a way as to share strokes, and the doubling mark added at bottom right. There is no firm evidence as to how these were to be read; possibly two morphemes were to be read, or possibly there was some kind of spoken contraction involved.

In Warring States bamboo texts there is a second kind of ligature, where a single compound character has the doubling mark but is meant to be read as two different morphemes. For example, the graph *bìng* 並 'together' with the doubling mark added is understood to be read as *bìnglì* 並立 'standing together'; the graph 並 itself is historically two 立 written side by side, and the use of the doubling mark to indicate 並立 requires that fact to be known to the reader.

The Internal Linguistic Structure of the Chinese Script

The Chinese script is famous for being nonphonetic. Although phonetic principles have plainly determined its development, it remains highly 'defective' in the technical sense: the sounds of speech are represented inconsistently, and are often totally concealed.

Figure 9 Pictographs: 馬, 立, 大 (top) and 口, 目, 月 (bottom).

Figure 10 Symbol-graphs: 一, 二 (top) and 五, 上 (bottom).

Primary Elements

Chinese characters are of two basic types: primary elements and compound characters made from two or more primary elements.

A primary element is one we recognize as being indivisible, so that no discrete linguistic meaning attaches to smaller components. Most primary elements are derived from 'pictographs' (*xiàngxíng* 象形 'form-depicting' characters), which stylize some physical object. Examples (from ca. 10th-century B.C.E. bronze inscriptions) are shown in Figure 9: the characters shown represent common Chinese words for 'horse,' 'to stand,' 'large' (in the top row) and 'mouth,' 'eye,' and 'moon, month' (bottom row). In their modern square script forms, the graphs are 馬立, 大 (top) and 口, 目, 月 (bottom).

Another traditional category of primary elements is the *zhǐshì* 指事, graphs that 'indicate a matter.' They are abstract and nondepictive. Figure 10 shows a few examples: 'one' 一, 'two' 二 (top) and 'five' 五, 'on top; to ascend' 上 (bottom). Relatively few primary elements are of this type.

Compounding: Extension of Primary Elements Through Polyvalence

Primary elements often appear as discrete graphs, but frequently we do not see them used in their primary meaning. Rather, the earliest attested usage is often as a loan for a near homophone or synonym standing at some distance from what we believe to be the primary sense. Such 'polyvalent' usage is known in Chinese as *jiǎjiè* 假借 ('loan') usage. Its best known form is semantic polyvalence – 'polysemy,' or the 'rebus' principle, in which one graph represents two words with different meanings but very similar sounds. Polysemy allows us to write words for which no obvious physical symbol can be found, by using any other word that has a sound that is the same or similar. Polysemy is a phonetic principle, and is the most fundamental linguistic principle involved in grasping the structure of Chinese script.

As an example, 立 represents an intransitive verb meaning 'to stand,' but we often see it used in other senses. One such usage is the transitive 'to erect,' although that is not usually considered to be *jiǎjiè* because the meaning 'to erect' is not now associated with a different graph or word. But 立 also stands for the word we now write 位 'place, position.' The ancient spoken word originally written 立 is reconstructed **g-rəp* (Mandarin *lì*), and 位 is reconstructed **rəps* (*wèi*); we believe the two words were alike enough in sound and meaning that the use of one to stand for the other would not have been a big jump for a literate reader. A third word sometimes written with 立 is 蒞 **g-rəps* (*qì*) 'to arrive at one's place.'

The three words standardly written 立, 位, and 蒞 are close enough that we can believe they may have been cognate, and so the use of a single form to stand for all three does not surprise us. But to date we have found no explicit native statement about these relationships, and so are forced to make deductions about the range of loangraph relationships. We also have no explicit word lists – lexicons showing sound, meaning, and a conventional graphic representation – older than about the 6th century C.E., and those from the 6th century are filled with archaisms and late standardizations. Consequently, our ability to reconstruct the early language and identify the words represented by graphs in excavated materials is still very limited.

A second form of polyvalence is 'polyphony' – writing a graph usually associated with one word to represent another word with a totally different sound but similar in meaning. Relatively few examples of this kind have survived the standardizing tendencies of the past 2200 years, but we do see occasional examples such as 屮, associated both with **hngrat* 'sprout' (a word long obsolete) and **'tshuʔ* 艸/草 'plant' in the received literature. In excavated ancient documents, however, there appear to be a great many examples of this kind.

Table 1 Phonetic compounds based on 刀

Graph	*Reconstruction*	*Meaning*	*Structure of graph*
刀	**'taw*	'blade, knife'	pictograph
到	**'taws*	'to arrive'	刀 disambiguated by the addition of semantic determinative 至 **tits* 'to arrive' (the element 刂 is an altered form of 刀)
召	**draws*	'to summon'	刀 disambiguated by the addition of semantic determinative 口 **khoʔ* 'mouth; oral'

Extension of Primary Elements Through Compounding

Primary elements are only a minute proportion of the total number of Chinese graphs. In most cases, a typical Chinese graph is a compound of two or more of them. Compounding is thought to have come about at an early date because of the intrinsic ambiguity of polyvalence. To resolve the ambiguity, 'determinative elements' were added, forming a compound graph. Determinatives may be either phonetic or semantic: they may give the reader a clue to the intended word through either sound or meaning.

The overwhelming majority of compounds involve the addition of a semantic determinative to a primary phonetic element that may once have been used polyphonically. Such 'phonetic compounds' (*xíngshēng* 形聲 'form and sound' graphs) make up the vast proportion of all of the Chinese characters attested from antiquity. Table 1 shows three graphs, two of which are compounds, differentiated semantically from the first, which was a polysemous primary graph.

From 到, another graph 倒 was derived for the word **'tawʔ* 'to fall down (said of a person)'. 倒 is two derivational steps away from 刀: in it, the compound 到 (associated with **'taws* 'to arrive' and **'tawʔ* 'to fall down') has been disambiguated by the addition of semantic determinative 人 **nin* 'person' for the word **'tawʔ* but not for **'taws*.

From 召 have sprung a whole series of secondary compound graphs, shown in Table 2.

And from 昭 another (tertiary) compound 照 has been derived, for **taws* 'to shine on' by the addition of the semantic determinative 灬 (火) **'hməj* 'fire'. None of the elements 至, 口, 人, 日, 手, 水, 言, 走, 音, 糸, 多, or 火 appear to contribute to the overall phonetic value of these graphs; in every case, our ability to read a character stems from the original association of the element 刀 with the sound **'taw*. Many scholars have proposed etymologizing these words so as to link them to the basic meaning of 刀 **'taw*, 'blade or knife': perhaps 'bright' and 'to shine' suggest the sharpness or glint of a blade, or perhaps 'summon' and 'command' suggest compulsion by force of arms. But that is speculation; there is no reason to assume that 刀 was used as anything except a token of sound in these graphs. If 'blade' and 'bright' are related, that is mainly a matter of the etymology of spoken words.

Our ability to describe early graphic evolution in Chinese is greatly complicated by two problems. First, compound graphs are rarely seen in their earliest meanings, and, second, primary graphs are rarely seen in the loan usages that we believe to have been disambiguated later as distinct phonetic compounds. Full documentation may never be possible, because it seems likely that many phonetic compound graphs known in post-Hàn times were perhaps formed directly *as compounds* without having gone through the process of disambiguation of a primary polyphonic pictograph.

A minority of compound graphs were formed by the addition of a phonetic element to an older pictograph. An example is the word *zhù* 'to cast in metal' now written 鑄 **tus* (?). The modern square-script form is a phonetic compound, with 壽 **duʔ* as the phonetic element and 金 'metal' **k(r)əm* as the semantic determinative. Figure 11 shows several ancient forms of 鑄: the three in the top row have in common the primarly elements 皿 'vessel' at the bottom and what appear to be two hands holding some sort of inverted vessel at the top. Between these two parts are variously 火 **'hməj* 'fire', 金 'metal' **k(r)əm*, and the element 㝵, whose reading and meaning are disputed but which appear to be the phonetic element in modern 壽. Of these three graphs, only the one containing 㝵 is recognizable to us as a phonetic compound, in which 㝵 specifies that a word resembling 壽 **duʔ* is intended; the other two must be understood as compounds of some sort. In the bottom row of Figure 11, we see a form containing 火, 金 and 㝵, followed by another form containing only 金 and 㝵 with 口 **'khoʔ* 'mouth' (an element of modern 壽). Both of these must be forebears of modern 鑄. Last is a form containing only 金 and 寸 **stuʔ* (?; likely variant of 手 'hand', phonetic in 守 **stuʔ* 'to protect'); this is also a phonetic compound graph, using a different phonetic element from the received form. In sum, it appears that early ways of writing 'to cast' were not phonetic, but that 㝵 was first added as a phonetic determinative and the complex pictographic elements gradually reduced to 金, which looks like a semantic determinative. But we can see that simple phonetic-plus-semantic structure

Table 2 Phonetic compounds based on 召

Graph	*Reconstruction*	*Meaning*	*Structure of graph*
昭	**taw*	'bright'	召 disambiguated by the addition of semantic determinative 日 **nit* 'sun'
招	**taw*	'to summon with the hand'	召 disambiguated by the addition of semantic determinative 手 **huʔ* 'hand'
沼	**tawʔ*	'pond'	召 disambiguated by the addition of semantic determinative 氵(水) **h(l)uʔ* 'water'
詔	**taws*	'to command'	召 disambiguated by the addition of semantic determinative 言 **ngan* 'to say'
超	**thraw*	'to exceed, surpass'	召 disambiguated by the addition of semantic determinative 走 **ʼtso(k)ʔ* 'to run'
韶	**daw*	'kind of ritual music'	召 disambiguated by the addition of semantic determinative 音 **(r)əm* 'music'
紹	**dawʔ*	'to connect'	召 disambiguated by the addition of semantic determinative 糸 **sə* 'thread'
貂	**tew*	'marten: kind of weasel'	召 disambiguated by the addition of semantic determinative 豸 **lreʔ*(?) 'any legless wild creature' (!)

Figure 11 Six bronze forms of *zhù* 鑄 'to cast in metal'.

is actually late in this graph, and developed following a different path than the 刀 compounds.

Semantic Compounds

Because compound characters are made of two or more primary elements, it is often thought that it is the *meanings* of those elements that combine to indicate the meaning of the whole compound. That is a misconception, one widespread in China as well as abroad. Chinese traditionally call such 'semantic compounds' *huìyì* 會義, graphs with 'meanings conjoined'. There are some graphs that (at present) are almost always explained as semantic compounds; for instance *lín* 林 'forest' is apparently composed of the element *mù* 木 'tree' doubled. But by far the overwhelming majority of compound graphs contain at least one patently phonetic element. Moreover, modern scholars continue to study those compounds that are ambiguous, and, in some cases, they have been plausibly explained as originally phonetic compounds in which the phonetic element has ceased to be recognized. A fine example is 鳴 **mreng* 'to crow,' apparently a compound of the elements 口 **ʼkhoʔ* 'mouth' and 鳥 **ʼtiwʔ* 'bird,' neither of which can be phonetic. However, it has been proposed by modern scholars that 口 is actually a polyphonic element, and that in addition to 'mouth' it also stands for a word meaning 'to call.' In addition to 鳴, common words using 口 phonetically for this sound are 名 **meng* 'name, to name' and 命 ** mrings* 'to command.' Presumably, one of the three words **mreng* 'to crow,' **meng* 'name,' and **mrings* 'to command' is what was originally intended by the use of the primary element 口 in all three graphs. Findings like this are disputed in many circles, however; the *huìyì*-type compound is part of the traditional lore of the Chinese script, whether or not it turns out to have a historical basis.

Character Structure and the Dictionary

Chinese dictionaries have been arranged by sound since at least the 6th century C.E., but how does one find a character if one doesn't know how it is pronounced? To solve this problem, Chinese dictionaries are also arranged by character structure. Usually, the semantic determinative, if there is one, is identified as the classifying element of a graph, and all the characters that have the same semantic determinative are placed together. For example, the characters 馮, 馳, 駁, 駕, 駱, 騎, and 贏 are all placed under 馬 in the dictionary, because 馬 is identified as a recurring determinative element in all of them.

Westerners generally call this element the 'radical' of the character, but the Chinese name (*bùshǒu* 部首) is better translated as 'classifier.' 'Radical' suggests that the determinative element is somehow the etymological 'root' of the graph, when in fact most semantic determinatives are late additions in compound characters; it is the original polysemous phonetic element that really deserves the name 'root.'

Chinantec: Phonology

D Silverman, Nanvet, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Chinantecan is a group of about 14 VSO languages within the Otomanguean family, spoken by approximately 90 000 people in northeastern Oaxaca, Mexico, having branched from the Otomanguean tree more than 16 centuries ago. The 14 major languages (where 'language' is defined as a speech community with mutual intelligibility not in excess of 80% with other communities) are Ojitlán, Usila, Tlacoatzintepec, Chiltepec, Sochiapan, Tepetotutla, Tlatepusco, Palantla, Valle Nacional, Ozumacín, Lalana, Lealao, Quiotepec, and Comaltepec. The first seven are northern languages and tend to be more innovative phonologically; the second seven southern languages are more conservative. Syllables are usually CV, with only a few post-vocalic elements, among them a nasal and/or laryngeals. Proto-Chinantec is reconstructed as possessing consonants *p, *t, *k, *k^w, *b, *z, *g, *g^w, *s, *m, *n, *ŋ, *w, *l, *r, and *j. Laryngeals *h and *ʔ could stand alone prevocalically, or could precede any of the voiced consonants. Additional consonant-glide clusters are reconstructed as well. The reconstructed tonal inventory includes *H, *L, *HL, *LH, and *HLH. Vowels included *i, *e, *a, *u, *ɨ, and *ə, as well as several diphthongs. The vowels may be augmented in a bewildering number of ways, however. In modern Comaltepec – the most conservative Chinantecan language – eight vowel qualities (i, e, æ, a, o, ʌ, ɨ, u) may be combined with five tonal qualities (L, M, H, LM, LH), two voice qualities (plain and aspirated), a nasality contrast, as well as a binary length contrast. The cross-classification of these 5 independent systems results in 320 possible nucleus qualities ($8 \times 5 \times 2 \times 2 \times 2$). Thus, a single vowel quality may possess up to 40 contrastive values.

Chinantec roots and words are usually monosyllabic. The rich inflectional system normally involves modification of root vowels, resulting in monosyllabic stems that bear a particularly high informational load. In Comaltepec, for example, a single syllable may contain not only the root but also (in the case of verb complexes) active/stative markers, gender markers (animate/inanimate), transitivity markers (intransitive/transitive/ditransitive), aspect (progressive/intentive/completive), and possibly subject pronoun clitics (two subsyllabic classes). Methods of stem modification involve nasalization, tone, length, phonation augmentation, and sometimes consonant changes. Additionally, certain irregular patterns are marked by ablaut. Due to their inherent inflection,

Chinantecan is a group of about 14 VSO languages within the Otomanguean family, spoken by approximately 90 000 people in northeastern Oaxaca, Mexico, having branched from the Otomanguean tree more than 16 centuries ago. The 14 major languages (where 'language' is defined as a speech community with mutual intelligibility not in excess of 80% with other communities) are Ojitlán, Usila, Tlacoatzintepec, Chiltepec, Sochiapan, Tepetotutla, Tlatepusco, Palantla, Valle Nacional, Ozumacín, Lalana, Lealao, Quiotepec, and Comaltepec. The first seven are northern languages and tend to be more innovative phonologically; the second seven southern languages are more conservative. Syllables are usually CV, with only a few post-vocalic elements, among them a nasal and/or laryngeals. Proto-Chinantec is reconstructed as possessing consonants *p, *t, *k, *k^w, *b, *z, *g, *g^w, *s, *m, *n, *ŋ, *w, *l, *r, and *j. Laryngeals *h and *ʔ could stand alone prevocalically, or could precede any of the voiced consonants. Additional consonant-glide clusters are reconstructed as well. The reconstructed tonal inventory includes *H, *L, *HL, *LH, and *HLH. Vowels included *i, *e, *a, *u, *ɨ, and *ə, as well as several diphthongs. The vowels may be augmented in a bewildering number of ways, however. In modern Comaltepec – the most conservative Chinantecan language – eight vowel qualities (i, e, æ, a, o, ʌ, ɨ, u) may be combined with five tonal qualities (L, M, H, LM, LH), two voice qualities (plain and aspirated), a nasality contrast, as well as a binary length contrast. The cross-classification of these 5 independent systems results in 320 possible nucleus qualities ($8 \times 5 \times 2 \times 2 \times 2$). Thus, a single vowel quality may possess up to 40 contrastive values.

Chinantec roots and words are usually monosyllabic. The rich inflectional system normally involves modification of root vowels, resulting in monosyllabic stems that bear a particularly high informational load. In Comaltepec, for example, a single syllable may contain not only the root but also (in the case of verb complexes) active/stative markers, gender markers (animate/inanimate), transitivity markers (intransitive/transitive/ditransitive), aspect (progressive/intentive/completive), and possibly subject pronoun clitics (two subsyllabic classes). Methods of stem modification involve nasalization, tone, length, phonation augmentation, and sometimes consonant changes. Additionally, certain irregular patterns are marked by ablaut. Due to their inherent inflection,

Table 1 Partial verb paradigm from comaltepec

hit (transitive/inanimate)	1s	1p	2	3
progressive	bah˩	ba˩	bah˩	bah˩
intentive	bah˥	bah˥	bah˥	bah˩
completive	bah˩	bah˥	bah˩˨	bah˩
hit (transitive/animate)				
progressive	bʌːn̥̍˧	bʌːn̥̍˧	bʌn̥̍˧	bʌːn̥̍˧
intentive	bʌːn̥̍˥	bʌːn̥̍˥	bʌn̥̍˥	bʌːn̥̍˧
completive	bʌːn̥̍˧	bʌːn̥̍˥	bʌːn̥̍˩˨	bʌːn̥̍˧

bare verbal roots do not exist as such in Chinantecan. All Chinantecan languages have a large number of verb classes, along with many lexical exceptions. Classes are differentiated by patterns of identity or nonidentity across aspect/person combinations. For example, in the partial paradigm for the verb 'to hit' shown in Table 1, some complexes are identical to others, while others are different. Verbs in this class will tend to show a similar pattern of identity and nonidentity across cells, while verbs in other classes show a different pattern.

Table 2 provides examples of stem inflection from Quiotepec (Robbins, 1968).

In at least some Chinantecan languages, the verb may be prefixed by a subject agreement marker for intransitive verbs, or by an object agreement marker for transitive verbs. Additional verbal prefixes include a negation marker, and tense and aspect markers (imperfect, past, hodiernal past, perfect, past imperfect, etc.). Unlike verbs, nouns do not typically display internal inflection, instead showing stability across inflectional augmentation. In Tepetotutla, for example, noun roots may concatenate with a quantifier, a gender-inflected numeral, a classifier, etc. In Lealao, constituents of the noun phrase may include a quantifier, the head, a modifier, a possessor, and a deictic marker, in that order, as well as a classifier prefix in some cases.

Stem complexes are obligatorily stressed. Posttonic and pretonic syllables are not stressed. Stressed syllables may possess greater phonological and morphological complexity than do unstressed syllables. In Sochiapan, unstressed syllables differ from stressed ones in displaying a more limited distribution of phonemes. Posttonic syllables in Palantla consist of a small list of words that do not contrast for tonal features. Pretonic syllables, while maintaining tonal contrasts, do not possess postvocalic elements, except in very careful speech. In Comaltepec, posttonic syllables consist of a limited set of clitics, person-of-subject inflectors (in verbs), and possessors (in nouns). Pretonic syllables consist of only several verbal prefixes and a few proclitics, and possess a smaller inventory of tone values. These syllables are not a site for further inflection, and thus do not

Table 2 Examples of stem inflection in Quiotepec (Robbins, 1968)

kʷoː˧	I give (something)
kʷoːˀ˥	I gave (something)
kʷo˧ʔo˥	thou givest (something)
kʷo˧ʔo˥	thou gavest (something)
kʷo˧ʔo˧	I give (something to someone)
kʷo˥ʔo˧	I gave (something to someone)
kʷo˧ʔo˥	thou givest (something to someone)
kʷo˥ʔo˥˨	thou gavest (something to someone)
kʷoːj̩˩ n̥nã˧	I give (something animate)
kʷoj̩˧ n̥nã˧	I gave (something animate)
kʷoːj̩˩ ʔnỹ˧	thou givest (something animate)
kʷoːj̩˧ ʔnỹ˧	thou gavest (something animate)
kʷoːj̩ʔ˩ n̥nã˧	I give (something animate to someone)
kʷoj̩ʔ˧ n̥nã˧	I gave (something animate to someone)
kʷoːj̩ʔ˩ ʔnỹ˧	thou givest, gavest (something animate to someone)

possess morphological complexity. In Quiotepec, too, stress falls on the major lexical classes (verbs, nouns, etc.); most pretonic syllables consist of inflectional material. Pretonic syllables only occur with single tones, never with tonal contours. In at least several Chinantecan languages, the vocalism of posttonic syllables is harmonically determined by the stem vowel. Tone may spread from stem to suffix as well.

Regarding Chinantecan stress, several languages are traditionally characterized as possessing either 'ballistic' stress or 'controlled' stress on stem syllables. In Palantla, Tepetotutla, Sochiapan, and Comaltepec, ballistic syllables have been characterized by an initial surge and rapid decay of intensity, and a loss of voicing of postvocalic elements; controlled syllables exhibit no such initial surge of intensity, displaying a more evenly controlled decrease of intensity, and a lack of postvocalic devoicing. Ballistic syllables tend to be shorter in duration than controlled syllables, and may possess a smaller inventory of tonal patterns. In at least several Chinantecan languages, ballistic syllables cross-classify with almost every other syllable type. Both oral and nasal vowels, both long and short vowels, preaspirated and preglottalized onsets and plain onsets, open and checked syllables, and nasally closed syllables, may all possess ballistic stress. Ballistic stress interacts most significantly with tone, tending to raise high tones and lower low tones. In Lalana, ballistic stress (considered postvocalic h in some analyses) may not occur with glottal checking, and may occur with only H, L, and HL tones, whereas controlled syllables reportedly also possess MH, LH, and HLH, and may be checked. In Lealao, only level tones (L, M, H, VH) may occur with ballistic stress, whereas controlled syllables may also occur with tonal contours (LM, LH). In Comaltepec, ballistic syllables may occur with almost any tonal pattern.

Table 3 Tone sandhi in Comaltepec

Non-sandhi context	*Sandhi context*	*Gloss*
to:˩	kwa˧ to:˥˩	give a banana
ŋɨh˩	kwa˧ ŋɨh˥˩	give a chayote
ku:˧	kwa˧ ku:˥˧	give money
hi˧	mɨ:˧ hi˧˥	I ask for a book
mohʔ˧	mɨ:˧ mohʔ˧˥	I ask for squash

The ballistic stress found in some Chinantec languages corresponds to tonal lowering in Ojitlán and Usila. Quiotepec is variously characterized as possessing ballistic accent or raised tones in these same contexts, often accompanied by postvocalic aspiration. The Chinantecan ballistic syllable corresponds to postvocalic aspiration in related Mixtecan and Otopamean languages, to prevocalic aspiration in related Popolocan languages, and to glottally 'interrupted' (CVʔV) syllables in the Chatino, Zapotec, and Tlapanec languages. Chinantecan ballistic syllables may derive from Proto-Otomanguean *CVh syllables (which may or may not have been phonetically realized as interrupted vowels). Indeed, recent phonetic and phonological investigations have recharacterized the ballistic phenomenon as largely laryngeally-based, involving postvocalic aspiration.

Segmental sandhi is rather limited in Chinantecan, although tone sandhi is widespread, being both phonologically and morphologically conditioned. The best-studied tone sandhi system is that of Comaltepec. Here, LH tones spread their H component on to a following vowel. Furthermore, M tones on unchecked controlled syllables (deriving from Proto-Chinantec H) trigger the presence of an H tone on the following syllable. Examples are shown in Table 3.

The State of the Art

If language is ultimately seated in the minds of individual speakers, as some linguists claim, then Chinese can be described as a collection of over 1.3 billion idiolects scattered around the world, in Mainland China, Taiwan, Hong Kong, and Singapore in particular. If on the other hand language is held to be the property of a speech community, as many linguists believe, Chinese is then an assemblage of numerous 'dialects' spreading over different continents and across time zones, some of which are so different that their speakers cannot even communicate with one another. In spite of the vast diversity, and even some mutual oral unintelligibility, all literate speakers can overcome the barrier imposed by the oral unintelligibility via reading (not aloud!) and writing. The writing script partly enables the users to transcend the differences of idiolects and dialects, and bridges the past and the present.

In this article, Chinese will be discussed within its two natural divisions: spoken Chinese and written Chinese. The former includes (1) the classification of dialects and their geographic and demographic

Table 3 Tone sandhi in Comaltepec

The State of the Art

If language is ultimately seated in the minds of individual speakers, as some linguists claim, then Chinese can be described as a collection of over 1.3 billion idiolects scattered around the world, in Mainland China, Taiwan, Hong Kong, and Singapore in particular. If on the other hand language is held to be the property of a speech community, as many linguists believe, Chinese is then an assemblage of numerous 'dialects' spreading over different continents and across time zones, some of which are so different that their speakers cannot even communicate with one another. In spite of the vast diversity, and even some mutual oral unintelligibility, all literate speakers can overcome the barrier imposed by the oral unintelligibility via reading (not aloud!) and writing. The writing script partly enables the users to transcend the differences of idiolects and dialects, and bridges the past and the present.

In this article, Chinese will be discussed within its two natural divisions: spoken Chinese and written Chinese. The former includes (1) the classification of dialects and their geographic and demographic

Figure 1 Classification of Chinese dialects.

distributions; (2) Putonghua as a lingua franca; and (3) a brief discussion plus sound illustrations of three major dialects. The latter includes (1) the writing script, and (2) the historical evolution of written Chinese from archaic Chinese to modern Chinese. The article concludes with a summative account of how Chinese, both spoken and written, is electronically processed.

Spoken Chinese

Although Chinese, like any other language in the world, is substantiated in idiolects, i.e., parole in the Saussurean term, they are thrown away after being used as evidence for language system construction i.e., the Chinese language. In other words, talking about Chinese, over 1.3 billion idiolects are generally ignored. What linguists are interested in is the various dialects evolved from them. The number of dialects depends on how fine-grained the researcher's scheme is intended to be. It is hardly a rare case that people in two villages only a dozen of miles apart cannot intelligibly communicate through speech.

Dialect Classification and Distribution

Chinese dialects can be classified by adopting a tree-like structure. The first branching-out from the trunk is the two major supergroups: Mandarin and non-Mandarin. Mandarin includes eight subgroups: Northeastern, Beijing, Beifang, Jiaoliao, Zhongyuan, Lanyin, Southwestern, and Jianghuai. The non-Mandarin group comprises nine subgroups: Jin, Wu, Hui, Gan, Xiang, Min, Yue, Pinghua, and Hakka. Each of the subgroups has its own clusters, each of which in turn encompasses local dialects (see Figure 1).

Geographically speaking, Mandarin is spoken in the following provinces and major cities: Heilongjiang, Jilin, Liaoning, the eastern part of the Inner Mongolia Autonomous Region, Shandong, Beijing, Tianjing, Hebei, Shanxi, Gansu, Qinghai, Ningxia Hui Autonomous Region, Sichuan, Yunnan, Guizhou, Guangxi Zhuang Autonomous Region, western part of Hubei, Chongqing, northern parts of Jiangsu, and Anhui. The total Mandarin-speaking population, based on the 1982 census, was about 662.23 million. Table 1 shows the demographic distributions among the subgroups of Mandarin. The demographic distributions of other non-Mandarin dialects are shown in Table 2.

Mandarin Chinese is often nontechnically regarded as an equivalent to Chinese, which was historically the language of the Han nationality. Thanks to massive immigration and frequent contact, Mandarin Chinese is spoken by non-Han ethnic peoples as well. Some members of the Hui nationality, for instance, who are of Mohammedan origin, adopt Mandarin as their mother tongue. Almost all members of the She and Manchu nationalities speak Mandarin Chinese. Conversely, some people of Han origin in Hainan Province speak the Be language instead of Mandarin.

Putonghua as Lingua Franca

Dialects create diversity and local identity, and at the same time impose constraints on communication and social interaction. A tension always exists between diversification and standardization of the language. Many campaigns have been launched in the long history of China in favor of standardizing both spoken and written Chinese. The policy of *shu tong wen zi* ('writing according to the same script') adopted in the Qin Dynasty (248–207 B.C.) was in fact a systematic reform undertaken by the imperial court to standardize the writing script. In the Sui Dynasty, Lu Fayan's (fl. 600 A.D.) *Qieyun* ('Guide to poetic rhyming') became a standard reference on pronunciation

Jin	45.70
Wu	69.75
Hui	3.12
Gan	31.27
Xiang	30.85
Min	55.07
Yue	40.21
Pinghua	2.00
Hakka	35.00
*Yet to be grouped	2.06
Total	315.03 (million)

for the generations to come, as well as for the reconstruction of ancient phonological systems. The campaign for the standardization of modern Chinese started as early as the last leg of the Qing Dynasty (1616–1911 A.D.) when the National Language Movement was vigorously launched as a part of the measures to revitalize the shattered country. It was argued that the nation could not be unified without a unified language. Guoyu ('national language') was initially envisaged and artificially constructed on the basis of some major dialects. This proved to be untenable, for it was next to impossible to promote such a language without natural speakers. New Guoyu ('new national language'), with the Beijing dialect as its base, was proposed and eventually adopted. Immediately after the founding of the People's Republic of China in 1949, language reform was put high on the government's agenda. Modern Standard Chinese, officially called Putonghua, was adopted as the national language. It uses the Beijing dialect for its standard pronunciation and northern dialects as its base input. Putonghua is officially stipulated to be the language of instruction at all levels of education, and of mass media.

The term Guoyu is still being used in Taiwan, while in Singapore it is called Huayu (i.e., Chinese). Putonghua, Guoyu, and Huayu are three different terms to refer to more or less the same Modern Standard Chinese.

Modern Standard Spoken Chinese

Phonology The phonological structure of Modern Standard Chinese is conceptualized more in traditional Chinese terms than otherwise. A syllabic structure has three essential components: initials, finals, and tones. The initials and finals are two segments of a syllable, while the tones are supersegmental, i.e., features superimposed on the segments. The initials are the sounds known as consonants in Western literature. The finals, i.e., vowels, have internal structures of their own: the medial and the root of the final, which is further decomposed into two: the main vowel and the syllabic terminal (see Figure 2).

The initial, the medial, and the syllabic terminal are not obligatory to make a Chinese syllable. A simple syllable can consist of a main vowel plus a tone only.

The possible initials, finals, and tones of Modern Standard Chinese are summarized in Tables 3, 4, and 5, respectively.

It is perhaps well-known now to the non-Chinese speaking world that Chinese tones are phonemic, that is, the same phonetic syllable pronounced in different tones will produce different words. The syllable /ma/ is the classic example: ma55 (mother), ma35 (hemp), ma214 (horse), ma51 (scold), and ma0, (a functional particle without a fixed lexical meaning).

While tones are properties of words, there are also intonations of utterances. The relation between the tone and the intonation is often metaphorized as small ripples (cf. word tones) riding on large waves (cf. utterance intonations). The interaction between the tone and the intonation results in an algebraic sum of the two kinds of waves.

Grammar It is generally held that, although Chinese dialects are so diversified that mutual unintelligibility in speech is not uncommon, they are conversely amazingly unified in matters of grammar. There are some minor divergencies found between dialects, for example, with regard to the order of direct and indirect objects, the Wu dialects and Cantonese differing from Mandarin Chinese. Cases like this, however, are extremely limited. It is quite valid to hold that there is one universal Chinese grammar.

At the risk of oversimplification, which is unavoidable in such a short essay as the present one, Chinese grammar, in comparison with English and other European languages, is pragmatically oriented. The subject and predicate in the grammar of Western languages are best viewed as the topic and comment in Chinese. The subject/actor and the predicate/action are treated as a special case of topic and comment.

For instance, *jiu bu he, yan chou* (word-for-word rendering: wine not drink, cigarette smoke) is understood as 'Talking about wine, I don't drink; but as for cigarettes, I do smoke.'

The topic-comment structure has something to do with the complaint often made by Westerners about Chinese saying 'no' but actually meaning 'yes.' Responding to the utterance *zhe shu bu hao* (word-for-word rendering: 'this book not good'), if the speaker also thinks that the book is not good, he will say *shi* ('yes'), meaning that he agrees with what the first speaker said about the book. While the English mind checks the statement against the fact, the Chinese mind expresses agreement or disagreement with the speaker. In other words, the Chinese mind tends to treat the speaker's utterance as setting up a topic, and the responder's job is to comment on the topic. The issue of the truth or falsehood of the statement becomes secondary.

Pragmatics One of the Chinese politeness maxims dictates that the speaker should denigrate him or herself, while elevating the other. This maxim has been codified in a range of lexical items. All the self-related expressions, including those referring to one's family members, relatives, properties, writings, and so on, are marked with denigration, whereas the other-referring expressions, including those referring to the other's family members, relatives, properties, writings, and so on, carry the force of elevation. For instance, a man referring to his own house will politely use *han she* ('cold living place'), but *fushang* ('mansion') to refer to the other's residence.

The self-denigration and other-elevation maxim also operates in compliment-taking. Complaints are made about Chinese failing to take a compliment gracefully. Hearing a compliment like *ni de yifu hen piaoliang* ('your dress is beautiful'), a Chinese lady will vigorously insist that it is very ugly indeed: *bu bu bu, chou shile* ('no no no, deadly ugly').

Written Chinese

In most languages, spoken and written forms are generally regarded as two functional varieties of one and the same language. The relation between spoken and written Chinese, however, cannot be dealt with so readily in the same way. Inscriptions incised on oracle bones, dated 1400–1100 B.C., are the earliest existent written records of Chinese. The inscriptions were not transcripts of the speeches of emperors or tribal kings. They can be regarded, at best, as setting up some of the earliest instances of a particular genre of written Chinese. By the time of the late years of Qing Dynasty (1616–1911) 3000 years or so later, the archaic written Chinese had become so different from the contemporary spoken Chinese that it would take years of dedicated study before one could read and write it. To make things even worse, the archaic written Chinese was prescribed as the medium of education. It was, and still is, no easier for students to learn it than it would be to learn a foreign tongue. Some language reform activists in the 1910s went on record arguing that archaic written Chinese

was partially to blame for the humiliating decline of the Chinese civilization following the time of the Tang dynasty (618–907).

Attempts to reform written Chinese thus had two aspects: the reform of the writing script and the reform of archaic written Chinese as the medium of education.

Writing Script Reform: Alphabetization Versus Simplification

he nature of the Chinese writing script has been disputed for years, as can be seen in the variety of English terms used to designate the marks on paper known in Chinese as *hanzi* (i.e., Chinese characters): pictographs, pictograms, ideographs, ideograms, phonograms, logographs, ideophonographs, lexigraphs, morphographs, sinographs, and so on. The evidence for the claim that the Chinese writing originated from picture-drawing is substantial. Table 6 shows four instances of pictographs taken from oracle bone inscriptions with their corresponding present-day characters.

It is apparent that the pictographs have evolved, through orthographic reforms, to such an extent that even those characters with highly iconicized origins as shown in the table have lost their picturesqueness. Chinese characters are constructed from five basic strokes (see Table 7) in a square space.

Picture-based character creation is only one of the many ways in which Chinese characters are constructed. Some philologists in the Han dynasty (206 B.C.–220 A.D.), on the basis of the then existent writings, abstracted six principles of character formation. Later studies show that only four of them are genuine: (1) zhi shi, the simple indicative principle; (2) xiang xing, the pictographic principle; (3) hui yi, the compound indicative principle; and (4) xing sheng, the semantic–phonetic principle. The pictographic method of character formation had ceased to be productive by the Han dynasty. The semantic–phonetic character formation has been the most productive of all, and the majority of Chinese characters are thus constructed. It is on this account that the Chinese writing system can be appropriately designated as being morphosyllabic.

A Chinese character can be as simple as one stroke (e.g., 一 'one'), or as complex as dozens of strokes (e.g., 齉 'snuffling'). Given a set of 11 834 characters, the average number of strokes per character is 11.5516, and 63 percent of the set is made of 12-stroke characters. Since it is quite a challenging task to learn to write such characters, there has been no shortage of appeals to reform the writing script. As early as the 1910s, some language reform activists argued for abolishing the characters altogether, to be replaced with a new alphabet script. This proved to be completely infeasible. The PRC government eventually adopted three reform measures: (1) a romanization alphabet known as Pinyin that is used to mark the pronunciations of characters; (2) a simplification scheme according to which 1754 characters would be simplified; and (3) a total of 1055 duplicate characters that were to be abolished.

The Reform of Archaic Written Chinese

Archaic written Chinese models the writings prevalent from the Spring and Autumn (770–476 B.C.) to the Later Han (25–220 A.D.) periods. Partially because the characters were immune to the dynamic changes of actual speech sounds over space and time, archaic written Chinese achieved, as it were, an independent symbolic existence. By the 1900s, it had no natural speakers. It did, however, have several potential rivals under the name *baihua wen,* literally meaning 'unadorned speech writing,' which was far closer to the contemporary vernacular speech. The reform movement basically dethroned archaic written Chinese and replaced it with the baihua wen that had been formerly much despised. The reform proved to be an uphill task, however, as it met with fierce resistance from die-hard adherents.

Three Major Dialects

As graphically shown in Figure 1, the non-Mandarin supergroup falls into nine subgroups of dialects, which of course can be further divided into smaller groups. In this section three dialects, Hong Kong Cantonese, Shanghainese and Fuzhou dialect, representing the Yue group, the Wu group and the Min group respectively, are examined as a window to show what the non-Mandarin dialects look like. They are highlighted here thanks to the demographic size (see Table 2) and relatively prestigious status they enjoy.

The Yue Group: Hong Kong Cantonese

Hong Kong Cantonese is one of the important varieties of the Yue group. It is spoken by 89 percent of Hong Kong's 6.4 million population (by the 1996 census) in family discourse. It is also used in some radio and TV programs, and as an instructional language in schools and university classrooms. English was the main official language in the former British colony, but its use actually was, and still is, quite limited. Since the return of sovereignty to China in 1997, Putonghua has become increasingly popular. Having said this, Hong Kong Cantonese still remains a true vernacular of the local people.

The term 'Cantonese' is derived from Guangzhou, the most influential city in southern China, which is known as Canton in English. Hong Kong and Guangzhou Cantonese are not noticeably different except that the former's lexicon has more English loan words than the latter's. In speech Cantonese and Mandarin or Putonghua are mutually unintelligible. Educated Cantonese speakers, however, use the standard form of written Putonghua. There are some spoken Cantonese words that have no corresponding Putonghua characters. Some Cantonese written words coined by local newspapers and in advertisements in Hong Kong are unintelligible to Putonghua readers.

Backed up by the economic and financial strength and influence of Hong Kong and Guangzhou, Cantonese is enjoying a prestige that is unprecedented for any regional dialect in China, and is the most studied of all the dialects. Grammars, dictionaries, and textbooks have been written to render it more like a language than a regional dialect.

Cantonese has 16 initial consonants. Unlike Mandarin, it has completely nasal syllables with *m* and *ng*

functioning as vowels. For instance, the Cantonese word for the Mandarin word *wu* ('five') is *ng*, which can only be a syllabic nasal terminal of a final in Mandarin. It has eight vowels, and two sets of consonants that can be syllabic terminals: (1) nasals:-m,-n,-ng; (2) unreleased consonants:-p,-t,-k. Its tone system is far more complex than that of Putonghua. The exact number of tones is not without controversy. Some hold that only six tones are clearly distinctive in Hong Kong Cantonese, although there can be up to nine tones in the Yue group.

The Wu Group: Shanghainese

The Wu group is spoken mainly in Shanghai, Southern Jiangsu Province, and a large part of Zhejiang Province. Historically the Suzhou Wu dialect enjoyed more prestige and esteem than the other regional varieties. When Shanghai established itself as an industrial and commercial center in China, it lost its glory and was replaced by Shanghainese, whose speakers seem to be eager to establish their own identity. Shanghainese speakers, who may speak fluent Putonghua, will loose no opportunity to code-switch to Shanghainese if they can be understood by an interlocutor, even at the risk of rudely shutting off any non-Shanghainese speakers from the conversation.

In comparison with Cantonese, Shanghainese is very much under-studied. Existent literature on it mainly consists of academic research papers. Like Cantonese, educated Shanghainese speakers write in written Putonghua, although there exist lexical items that are unique to the dialect.

The term Shanghainese refers to the majority speech of downtown Shanghai. It has 28 initials (i.e., consonants), and 43 finals (i.e., vowels). One of its hallmark features (and also of the Wu group) is a three-way distinction in the initial consonants p, p', and b, which become a two way distinction, p, and p', in Putonghua. Although Wu dialects have seven or eight tones, tones 4, 5, and 6 have been lost as separate categories, which results in five tones in Shanghainese: (1) high level (53), (2) level high (35), (3) low level (13), (4) high + a glottal stop (5), and (5) low + a glottal stop (1).

The Min Group: Fuzhou Dialect

The Min group is mainly spoken in Fujian, Taiwan, Hainan, as well as some areas in Guangdong, Zhejian, Guangxi, and Jiangxi. It is by no means a homogeneous group. On the contrary, even within Fujian Province six subgroups can be identified, one of which is known as the Min eastern subgroup, with the Fuzhou dialect as its prototype. Mutual communicability within this eastern subgroup is quite low.

Table 8 Sample usage in Fujian dialect

Putonghua	*Fujian dialect*	*English translation*
水稻 (shuidao)	粘	rice
书信 (shuxin)	批	letter
冷 (leng)	清	cold
哭 (ku)	啼	cry
逃跑 (taopao)	走	escape
走 (zou)	行	walk

Historically the Fuzhou dialect was understood to cover an area of 11 counties. The present-day use of the term is much restricted to the speech of the locals in downtown Fuzhou. Phonologically it has 15 consonants, 46 vowels including diphthongs, and 7 tones. One of the striking features of the Fuzhou dialect in comparison with Mandarin is that it has preserved a great many archaic words or usages. For instance, the word for 'rice' is 粘 in Fujian dialect, which is totally obsolete in Putonghua. For another instance, the word 批 in Fujian dialect is used to mean a letter, a usage found only in archaic Chinese. Table 8 lists some more instances.

Sound Illustrations

The phonological differences between Putonghua, Hong Kong Cantonese, Shanghainese, and Fujian dialects can be illustrated by the ways four natural objects – the sun, the moon, stars, and thunder – are lexicalized and pronounced (see Table 9).

Chinese Information Processing

At the early stage of computer technology, processing Chinese characters seemed to be such a forbidding task that calls for the romanization of the Chinese writing system were made again, but initial conceptions of the problem proved to be exaggerated. The national standard GB 2312–80, established on the basis of ISO 646 and officially coming into effect in 1981, provides a standard scheme of coding 6763 characters, which are subdivided into two groups according to the frequency of usage: the most frequent set, and the less frequent set. The most frequent set of 3755 characters is assumed to be 99.9% adequate for general usage (based on a statistical study of lexical frequency made in 1974). The GB 2312–80 standard met the demands of hardware and software development and exchange of information for general purposes, but it soon had to be amended as new demands arose. In 1994, a standard coding scheme for two supplementary sets consisting of 7237 and 7039 characters was officially

Note: The characters are transcribed in IPA symbols. The superscripted numbers are tone types with 1–5 values.

announced. As GB 2312–80 was designed to accommodate simplified characters, the new GB 12345–90 was introduced for nonsimplified characters that are maintained in Taiwan and Hong Kong. Nowadays, character recognition for both print fonts and handwriting is commercially available. Text-to-speech synthesis and production in the genre of journalistic texts has achieved a high degree of naturalness. The character script and lexical tones, which were thought to be two major obstacles for Chinese information processing, are no longer condemned, but appreciated as features with a flavor of real Chinese.

Chinese (Mandarin): Phonology

S Duanmu, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Chinese is the first language of over 1 billion speakers. There are several dialect families of Chinese (each in turn consisting of many dialects), which are often mutually unintelligible. However, there are systematic correspondences among the dialects and it is easy for speakers of one dialect to pick up another dialect rather quickly. The largest dialect family is the northern family (also called the Mandarin family), which consists of over 70% of all Chinese speakers. Standard Chinese (also called Mandarin Chinese) is a member of the northern family; it is based on the pronunciation of the Beijing dialect. There are, therefore, two meanings of the term Mandarin Chinese, one referring to the northern dialect family and one referring to the standard dialect. To avoid the ambiguity, I use Standard Chinese (SC) for the latter meaning. SC is spoken by most of those whose first tongue is another dialect. In principle, over 1000 million people speak SC, but in fact less than 1% of them do so without some accent. This is because even Beijing natives do not all speak SC.

SC has five vowels, shown in Table 1 in IPA symbols (Chao, 1968; Cheng, 1973; Duanmu, 2002; Lin, 1989). [y] is a front rounded vowel. When high vowels occur before another vowel, they behave as glides [j, ɥ, w]. [i] and [u] can also follow a nonhigh vowel to form a diphthong. The mid vowel can change frontness and rounding depending on the environment. The low vowel can change frontness but not rounding.

The consonants of SC are listed in Table 2; sounds with limited distribution are in parentheses. For most speakers, [ŋ] cannot occur in syllable-initial position. In syllable-coda position, only [n] and [ŋ] can occur. The palatals do not contrast with [ts, ts^h, s], [ʈʂ, ʈʂ^h, ʂ], or [k, k^h, x]; the palatals only occur with front vowels or front glides, but the other three sets do not. Because some speakers pronounce the palatals as [ts^j, ts^{jh}, s^j], it is possible to analyze a palatal as a combination of a dental and a front vowel. The retroflex liquid (sometimes written as a fricative [ʐ]) is not a trill but an approximant (and has no lip rounding, unlike that in English); because SC does not have a trill, I transcribe it as [r] instead of [ɹ]. The retroflex series [ʈʂ, ʈʂ^h, ʂ, r] is a major characteristic of SC speakers from Beijing. SC speakers from other areas often replace [ʈʂ, ʈʂ^h, ʂ, r] with the dentals [ts, ts^h, s, z]. The unaspirated stops and affricates [p, t, k, ʈʂ, ts] can become voiced [b, d, g, ɖʐ, dz] when they occur in an unstressed syllable.

SC also has two syllabic consonants [z] and [r] (or [ʐ]). They were previously thought to be special vowels, probably because it was believed that every syllable must have a vowel. [z] is used when a syllable starts with [ts], [ts^h], or [s] and when there is no vowel in the rime; it can be seen as the extension of the [s] element into the rime, where it becomes voiced. [t] is used when a syllable starts with [ʈʂ], [ʈʂ^h], [ʂ], or [r] and when there is no vowel in the rime; it can be seen as the extension of the retroflex element into the rime. SC also has a couple of syllabic nasals, which are usually interjections.

The SC syllable can made of up to four sounds – CGVX, where C is a consonant, G is a glide, V is a vowel, X is a nasal or an offglide of a diphthong, and VX is the rime. When both C and G are present, they are realized as one sound C^G, where G is the secondary articulation. Thus, the SC word [s^{w}ei] 'age' is phonetically quite different from the English word [swei] *sway*. SC also has a suffix [r], which changes the rime of the syllable it is attached to from VX to Vr and adds a retroflex quality to the nuclear vowel. In other words, the [r] suffix can lead to loss of contrast in the original coda.

SC has two kinds of syllables, which can be called full (or regular) syllables and weak syllables. Full syllables (mostly monosyllabic content words) have tones and are long. Weak syllables (mostly grammatical words) are short and do not have their own tones. A full syllable can sometimes change to a weak syllable, in which case it loses its underlying tone and

Table 1 Standard chinese vowels

High	i	y	u
Mid	ə		
Low	a		

Table 2 Standard chinese consonants

Labial	*Dental*	*Palatal*	*Retroflex*	*Velar*
p	t			k
p^h	t^h			k^h
	ts	(tɕ)	ʈʂ	
	ts^h	(tɕ^h)	ʈʂ^h	
f	s	(ɕ)	ʂ	x
m	n			(ŋ)
	1		r	

undergoes rime reduction and shortening. In syllable theory, full syllables are heavy and have two moras each, whereas weak syllables are light and have one mora each. In other words, in weak syllables the vowel is short. In full syllables, the vowel is short when the rime is VC or VG and long when the rime is V.

In the electronic dictionary CMUDICT, English has approximately 10 000 monosyllables (excluding homophones). In contrast, SC has a very small syllable inventory, only approximately 400 syllables excluding tones (or approximately 1300 syllables including tones). It is a puzzle why SC uses so few syllables, especially when many times more seem to be available. For example, given about 20 Cs, three Gs, five Vs, and five Xs, there are approximately 2000 possible CGVX combinations (excluding tones), yet just 400 are used. It turns out that two-thirds of the unused forms are ruled out by two requirements. The first is that C and G cannot have the same place of articulation, which follows from the analysis that C^G is a single sound because in a single sound each place feature can be used just once. The second requirement is that V and X cannot have opposite values for [round] or [back].

There are four distinctive tones on full SC syllables. Weak syllables may get tone from certain intonational environments; otherwise, they remain toneless, which is phonetically a low pitch. The four distinctive tones are high, rise, low, and fall. The pitch range of the tones can vary according to stress, whereby a syllable with greater stress has a wider pitch range (Shen, 1985). Using standard tonal features, according to which contour tones are made of two (or more) level tones, the four tones are represented in (1), where the vowel is long because it is in a V rime.

(1)

Tone name	First	Second	Third	Fourth
Tone feature	H	LH	L	HL
Syllable	maa	maa	maa	maa
Gloss	'mother'	'hemp'	'horse'	'scold'

In the alphabet system Pinyin, the words in (1) can be written *ma1*, *ma2*, *ma3*, and *ma4*, where vowel length is not represented and tones are represented by the digits 1–4. The first, second, and fourth tones have normal voice quality, but the third tone has a murmured voice quality. The third tone may also begin with a slight dip in pitch, which does not seem to be phonologically relevant. In final position, the third tone can optionally end with a rise, in which case it is phonetically extra long. Phonologically we may represent it with three moras, exemplified in (2). Such a syllable often has an amplitude break or a glottal stop in the middle, and to some people it sounds like two syllables.

(2) L H
maaa
'horse'

Of the 1300 or so SC syllables (including tones), most are full syllables, in which the four tones are fairly evenly distributed, as shown in Tables 3 and 4. In Table 3, one sees that there are slightly fewer second tones than other tones, but not by a lot. In Table 4, one sees that most syllables have four or three tones each, and only a small number of syllables have two or one tone each.

According to a text corpus of over 45 million Chinese character tokens (Da, 2000), there are over 6000 different Chinese characters, most of which represent monosyllabic words. This means that each SC syllable represents approximately 15 words excluding tones or five words including tones. The homophone load is not distributed evenly, as Figure 1 shows. The top 15 SC syllables are shown in (3), where the number of words a syllable represents (ignoring tones) is shown in parentheses. One might think that the most frequent syllables are the most natural or unmarked, namely, those that children learn first or those that are most common in the world's languages, such as [ba],

Table 3 Frequency of tones

Tone	*First*	*Second*	*Third*	*Fourth*	*All*
Number	337	255	316	347	1255

Table 4 Frequency of tones

Tones per syllable	*4*	*3*	*2*	*1*	*All*
Number of such syllables	178	130	59	35	402

Figure 1 Homophone density in Standard Chinese (ignoring tones), based on the analysis of 6000 characters listed in Da (2000). Most syallables represent fewer than 20 words each, but the syllable [ji] represents over 100 words.

[ma], or [ta]. However, many of the syllables in (3) do not seem to be unmarked syllables.

(3) pi (51), tɕy (51), wei (53), wu (55), ʂɿ (58), tɕan (61), ɕi (64), ɻan (64), tɕʰi (66), li (71), tʂɿ (72), fu (73), ɻy (90), tɕi (93), ji (106)

Most English monosyllables represent just one word each. Because Chinese has so many homophones, a natural question is: How does Chinese avoid ambiguity in speech? The answer seems to be that most ambiguities are clarified by context. For example, although *sun* and *son* are homophones in English, there are few contexts in which they would cause ambiguity.

Despite the large number of homophones, the syllable inventory of Chinese continues to decrease. SC no longer allows [p, t, k] or [m] in syllable-final position, although some other dialects do. Shanghai has lost all diphthongs, and its tonal inventory has reduced to just two. In all likelihood, SC is moving in the direction of further reduction. For example, SC does not make use of such contrasts as [wi] vs. [wei] or [ji] vs. [i], which English does (consider *we* vs. *way* and *yeast* vs. *east*). In addition, about 200 of the 1300 syllables are now rarely used. From a functional point of view, it is a mystery why the high homophone density has not prevented syllable loss in SC or at least slowed it down. A possible answer, paradoxically, is that high homophone density may in fact speed up syllable loss. Studies on frequency effects show that frequent words (Bybee, 2001) are more likely to undergo reduction than infrequent words. Because Chinese has fewer syllables than English, Chinese syllables are used more frequently and so they are more likely to undergo reduction and loss of contrasts.

In disyllabic English words and phrases three kinds of stress differences can be distinguished. In words such as *Peter*, *Anna*, and *panda*, the first is clearly stressed and the other not. In such cases, the stressed syllable is longer, has an unreduced vowel, and has a pitch accent. In contrast, the unstressed syllable is short, has a reduced vowel, and has no pitch accent. In words such as *blackboard* and *pancake*, the stress difference is also clear. Although both syllables are heavy and have an unreduced vowel, one syllable has a pitch accent and the other does not. In expressions such as *Red Cross*, *real deal*, and *red-hot* (adjective), the stress difference is no longer obvious; in each case, both syllables are heavy, have an unreduced vowel, and have a pitch accent. As a result, they are sometimes thought to have equal stress.

When a full SC syllable occurs next to a weak one, their stress difference is like the first English case (*Peter*, *Anna*, and *panda*). When two (or more) full SC syllables occur together, they all have tones and so their stress difference is not obvious; this is similar to the third English case (*Red Cross* and *real deal*). Now, in English the first two cases are quite common, and so stressed syllables often stand out. In Chinese, on the other hand, full syllables often occur together, and so stressed syllables often do not stand out. This may have contributed to a common view that there is no stress in Chinese.

The difference between full and weak syllables in SC can be explained in terms of moraic trochee – a full syllable has two moras, so it forms a foot and has stress. However, Chinese also uses disyllabic feet. For example, the disyllabic foot is used in poetic templates, and it is also a domain for certain kinds of tone sandhi. In addition, a minimal expression should be disyllabic. If a noun is monosyllabic, a semantically redundant syllable is often added. Thus, an SC speaker usually cannot say *Fa* 'France' or *Wang* 'Wang', but must say *Fa Guo* 'France country', *Lao Wang* 'old Wang', or *Xiao Wang* 'little Wang'. In contrast, *Sudan* 'Sudan' and *Yindu* 'India' can be said by themselves (and adding 'country' to them would be odd). The disyllabic requirement has created a large dual vocabulary whereby many words have two forms, a monosyllabic form and a disyllabic form. The disyllabic form is a compound in structure but a single noun in meaning, and it can be called a pseudo-compound. Some examples are shown in Table 5.

It is commonly thought that the creation of disyllabic words is triggered by homophone density. However, the common view cannot explain why monosyllabic names need another syllable, even though there is no ambiguity, such as when you address someone in person. A more likely reason for the creation of pseudo-compounds is to fill a disyllabic foot (Duanmu, 1999b).

A disyllabic noun (or compound) can be heavy-heavy (two full syllables) or heavy-light (a full syllable and a weak syllable), but not light-heavy. This suggests that the disyllabic foot is trochaic. However, when a heavy-heavy noun is spoken in isolation, the second syllable is often longer and appears to have slightly more stress. This has led to the view that Chinese has final stress (Chao, 1968; Hoa, 1983).

Table 5 Pseudo-compounds

Pseudo-compound	*Literal meaning*	*Gloss*
mei-tan	coal-charcoal	'coal'
shi-jian	time-interval	'time'
shang-dian	business-store	'store'
jin-qian	gold-money	'money'
lao-hu	old-tiger	'tiger'

But when a heavy-heavy noun is in nonfinal position, its second syllable no longer has extra duration (Feng, 1985; Wang and Wang, 1993). It seems, therefore, that the extra duration of a final full syllable is due to prepause lengthening and the trochaic analysis fares better overall.

The discussion so far suggests that a disyllabic word contains both moraic trochee and syllabic trochee (Duanmu, 1999a). The structure is shown in (4), which can be called a dual-trochee.

```
(4)                    heavy-light     heavy-heavy
                          x               x
   Syllabic trochee:    (σ   σ)         (σ     σ)
                         /\   |          /\     /\
   Moraic trochee:      (mm) .m         (mm) . (mm)
                          x               x      x
```

The dual-trochee distinguishes three degrees of stress: (1) a heavy syllable that heads a syllabic foot, (2) a heavy syllable that does not head a syllabic foot, and (3) a light syllable. The cases are easy to distinguish in English: (1) an unreduced vowel and a pitch accent (first syllable in *Peter*, *pancake*, or even *city*, if the last word is syllabified as *cit.y*), (2) an unreduced vowel but no pitch accent (second syllable in *pancake*), and (3) a reduced vowel and no pitch accent (second syllable in *Peter* or *Anna*). In Chinese, (1) and (2) are hard to distinguish because they both have tones and unreduced rimes; however, (3) is easy to distinguish from (1) and (2) because it has a reduced rime and no tone.

Because Chinese uses pitch contour (tones) to contrast word meanings, intonation is often expressed not as pitch variation on lexical words themselves, but as boundary tones that are added after lexical tones. Two examples are shown in (5) and (6).

```
(5) Tone          Intonation
    LH        +   L            →   LHL
    nan                            nan
    'difficult'   'affirmation'    'Surely difficult!'

(6) Tone          Intonation
    HL        +   H            →   HLH
    mai                            mai
    'sell'        'question'       'Sell?'
```

The boundary tones can also occur on what might be called intonation syllables. For example, the boundary tone in (5) can occur on [a] or [ou], and that in (6) can occur on [ma].

Many Chinese dialects have tone sandhi, whereby syllable tones change in context. The most well-known tone sandhi in SC is Third Tone Sandhi, by which a third tone changes to a second tone when another third tone follows, or T3 T3 → T2 T3. In an expression made up of many third tones, the resulting change can be quite complicated. To understand the change we must first understand the formation of syllabic feet, which in turn depends on syntax (Shih, 1986; Shen, 1994; Chen, 2000; Duanmu, 2002). Thus, Third Tone Sandhi offers an excellent case for the study of the interaction between phonology and syntax.

In summary, Chinese differs from languages such as English in a number of ways (such as a lack of polysyllabic words, a small inventory of syllables, high homophone density, a dual vocabulary, and the use of distinctive tones). However, the difference is only apparent. Under careful analysis, Chinese also observes linguistic principles similiar to those in other languages (such as foot structure, the behavior of heavy vs. light syllables, and the effect of frequency on syllable reduction).

Chinese as an Isolating Language

J L Packard, University of Illinois, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

If we use the term 'isolating' in what is perhaps its simplest and most often used sense – referring to whether the words of a language are mostly monomorphemic (*see* **Classification of Languages**) – then Chinese can be considered only a moderately isolating language, because Chinese has at least as many multimorphemic as it has monomorphemic words. The term isolating, however, has also been used to refer to whether the morphemes of a language are clearly identifiable, defined by the following properties: (1) whether morpheme boundaries in the language are sharply defined, (2) whether there is only a single distinct morphemic identity represented within a defined morpheme boundary space (i.e., the extent to which there is no overlapping exponence; (*see* **Classification of Languages**), and (3) whether morphemes in the language have a single, invariant phonological form. If we define an isolating language based on an identifiable morphemes criteria, then Chinese scores relatively high on the 'isolating language' scale. It can be profitably studied using both definitions of the term.

Isolating Defined as Having Monomorphemic Words

The definition of isolating language as monomorphemic relies on whether words in a language appear without the obligatory affixation of grammatical morphemic information. This property was intended to contrast with languages such as Russian and Latin in which word roots are generally bound content forms that require affixation of grammatical morphemic information (indicating such properties as case, number, or gender) when they occur in context. For example the Russian root for 'book' (*knig-*) must be augmented with an inflectional ending that reflects case or number (*knig-u* book-ACC.SING; *knig-i* book-NOM.PL), and cannot appear as a bare stem in isolation.

Languages like Chinese whose words occur without such obligatory grammatical marking are considered isolating because the words in such languages may appear in bare form without the necessity of adding morphemic information. The absence of obligatory affixation means that words in such languages will tend to contain fewer morphemes on average, giving rise to the monomorphemic word definition of isolating language.

Chinese as an Isolating Language

J L Packard, University of Illinois, Urbana, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

If we use the term 'isolating' in what is perhaps its simplest and most often used sense – referring to whether the words of a language are mostly monomorphemic (*see* **Classification of Languages**) – then Chinese can be considered only a moderately isolating language, because Chinese has at least as many multimorphemic as it has monomorphemic words. The term isolating, however, has also been used to refer to whether the morphemes of a language are clearly identifiable, defined by the following properties: (1) whether morpheme boundaries in the language are sharply defined, (2) whether there is only a single distinct morphemic identity represented within a defined morpheme boundary space (i.e., the extent to which there is no overlapping exponence; (*see* **Classification of Languages**), and (3) whether morphemes in the language have a single, invariant phonological form. If we define an isolating language based on an identifiable morphemes criteria, then Chinese scores relatively high on the 'isolating language' scale. It can be profitably studied using both definitions of the term.

Isolating Defined as Having Monomorphemic Words

The definition of isolating language as monomorphemic relies on whether words in a language appear without the obligatory affixation of grammatical morphemic information. This property was intended to contrast with languages such as Russian and Latin in which word roots are generally bound content forms that require affixation of grammatical morphemic information (indicating such properties as case, number, or gender) when they occur in context. For example the Russian root for 'book' (*knig-*) must be augmented with an inflectional ending that reflects case or number (*knig-u* book-ACC.SING; *knig-i* book-NOM.PL), and cannot appear as a bare stem in isolation.

Languages like Chinese whose words occur without such obligatory grammatical marking are considered isolating because the words in such languages may appear in bare form without the necessity of adding morphemic information. The absence of obligatory affixation means that words in such languages will tend to contain fewer morphemes on average, giving rise to the monomorphemic word definition of isolating language.

As it turns out, many (if not most) Chinese words are in fact dimorphemic, consisting of either (1) two free content morphemes (compound word), (2) one free and one bound content morpheme or two bound content morphemes (bound root word), (3) a free or bound content morpheme plus a word-forming affix (derived word), or (4) a free content morpheme plus an inflectional affix (grammatical word; see Packard, 2000 for further details). However, most dimorphemic Chinese words are either compound words or bound root words, and so the multimorphemic status of Chinese words is generally not due to the presence of affixation. Moreover, when Chinese words do contain affixes, they are never obligatory in the sense that they are required in the default case, as seen in the Russian example above.

Chinese affixes are, nonetheless, sometimes obligatory in an alternative sense: if a property in question is selected to be expressed by the speaker, then the use of the affix concomitant with that property is a required element. Some common examples of this obligatory marking of an optionally selected property in Chinese are the use of classifiers with nouns, the marking of plural numbers on human pronouns, and the use of aspect marking on verbs.

Classifiers are word-forming morphemes that are required when nouns are modified by a number and/or a determiner. For example, the noun *shu* 'book' generally occurs in context in bare form with no grammatical marking whatsoever. But when *shu* is modified by a number such as *san* 'three' or a determiner such as *na* 'that,' the classifier *ben* 'volume' must occur between the modifying element and the noun, yielding *san-ben shu* and *na-ben shu* for 'three books' and 'that book' respectively.

In the case of human pronouns, the personal pronouns *wo* 'I/me,' *ni* 'you,' and *ta* 'he, she' are obligatorily marked with the plural suffix *-men* when the referent is plural in number, to yield *women* 'we, us,' *nimen* 'you (pl),' and *tamen* 'they, them.'

Verbs in Chinese may occur with inflectional suffixes that express various forms of grammatical aspect, that is, that refer to the activity profile of the event represented by the verb. For example, the verbal aspect marker *-le* (note that this is the *-le* that affixes to and has scope over the verb, and not the *le* that occurs in sentence-final position and has scope over the sentence) indicates that the event associated with the verb has been completed, the verbal aspect marker *-guo* indicates that the event associated with the verb has occurred at least once, and the verbal aspect marker *-zhe* indicates that the action represented by the verb is ongoing or continuous.

In Chinese, the obligatory marking of a selected property as seen in classifiers, human plural pronouns, and verbal aspect contrasts with cases in which the marking of a selected property is optional, as with plural marking on regular human nouns. When a human noun is transparently plural in number, the addition of the suffix *–men,* which would explicitly represent a plural number, is optional. For example, in both of the following examples the Chinese noun that translates into English as 'teachers' refers unambiguously to a set that contains multiple members.

(1) laoshi dou you shu
teacher all have book
'the teachers all have books'

(2) laoshimen dou you shu
teacher-PL all have book
'the teachers all have books'

Both examples refer to 'teachers' as a plural concept but only the second overtly marks the plural number with the suffix *-men*. The two examples are identical in meaning, but the second explicitly marks the plural while the first does not.

If Chinese is examined as an isolating language based on its use of monomorphemic words, it is worthwhile to consider in concrete terms where Chinese should be located on the monomorphemic word scale. The contemporary Chinese novel *Shui Ru Da Di* by Wen Fan (2004; Beijing: People's Literature Publishing House) provides a typical sampling. If we examine the first 100 words in the third paragraph on page 16, we find that 51 (51%) of the words are monomorphemic (if by token; 35 words or 47.2% if by type), 45 (45%) of the words are dimorphemic (if by token; 35 words or 47.2% if by type), and 4 words (4% if by token, 5.4% if by type) contain more than two morphemes. If counted by type, 47.3% of the words are monomorphemic, and 52.7% are multimorphemic.

In addition, the average number of morphemes per word token for that hundred-word sample is 1.54. This figure may be compared with the 1.06 morphemes-per-word cited for Vietnamese (perhaps the most purely isolating language using this criterion), 1.68 for modern English, and 3.72 for Eskimo (*see* **Classification of Languages**). In sum, if the concept of monomorphemic words is used as the defining criterion, Chinese must be considered only moderately isolating.

Isolating Defined as Having Clearly Identifiable Morphemes

To determine where Chinese belongs on the isolating language scale using the 'identifiable morpheme' criterion, the first property to consider is sharply

defined morpheme boundaries. In Chinese, morpheme boundaries are nothing if not clearly defined. There is generally no question where one morpheme ends and another one begins in any Chinese utterance. Even in cases of affixation in which the phonological form of the stem is affected, it is quite clear which part of the affixed word belongs to the stem and which part belongs to the affix.

To illustrate, consider the following examples of *-er* (phonetically [ər]) diminution suffixation (data from Cheng, 1973; in IPA, tones not marked). The *-er* suffix often makes only a negligible semantic contribution to the derived word, but it is the affixation operation that has the greatest phonological effect in (Mandarin) Chinese.

The *-er* suffix attaches to words with varying degrees of phonological effect on the stem and on the affix itself. In examples (1)–(3) of Table 1, the *-er* suffix is appended to the stem with the [ə] vowel of the suffix dropped in favor of stem vocalic elements, and with no effect on the phonological form of the stem. In (4), the [ə] vowel of the suffix is dropped and the stem final velar nasal [ŋ] is lost, but its nasality is retained in the form of nasalization on the stem nuclear vowel, that is, [ɑ̃]. In (5), the [ə] vowel of the suffix is dropped and the stem final apical nasal [n] is lost, but its nasality is not retained as in (4). In (6), we see a stronger contribution from the suffix, since it retains its [ə] vowel. In (7), the suffix is appended in unaltered form, and the stem final [n] is displaced. In (8)–(10), the suffix is appended in unaltered form, replacing various parts of the stem final, including its complete replacement in (9) and (10).

The examples in Table 1 demonstrate that even though suffixation of *-er* results in a good deal of phonological variability on both stem and affix, in all cases the resulting derived words contain phonological strings that can be unambiguously attributed to either the stem or the affix, and the phonological identities of the participating morphemes remain clear.

Table 1 Some phonological effects of *-er* suffixation

	Noun	*Noun plus* -er *([ər]) suffix*	*Meaning*
(1)	niou	niour	'ox'
(2)	uɑ	uɑr	'frog'
(3)	kɣ	kɣr	'song'
(4)	gɑŋ	gɑ̃r	'jar'
(5)	p'an	p'ar	'pan'
(6)	i	iər	'clothes'
(7)	in	iər	'seal'
(8)	kuei	kuər	'ghost'
(9)	ci	cər	'word'
(10)	pei	pər	'cup'

Thus, the sharply defined morpheme boundary aspect of the identifiable morpheme criterion for isolating language makes Chinese appear quite isolating indeed.

The second criterion for identifiable morphemes is the existence of overlapping exponence. 'Overlapping exponence' refers to the occurrence of more than one grammatical property within a single affix. For example, in the case of the *-us* ending on the Latin word *lupus* 'wolf', where the *-us* encodes both accusative case and singular number, there is no way to confer an independent phonological identity upon a portion of the *-us* suffix that encodes the accusative and a part that encodes the singular. In Chinese, there are no affixes that do such double duty by systematically encoding more than one grammatical meaning in a single affix. Therefore, Chinese is clearly an isolating language in view of this property.

The third necessary property of identifiable morphemes is invariance of phonological form. Chinese morphemes do commonly change from their citation phonological forms when they appear in context. Such phonological variation, however, is virtually always completely determined by phonological environment. This is in contrast with languages such as Russian and Latin, where allomorphic variation in general is grammatically conditioned, and generally occurs independent of phonological context. In Chinese, the shift from citation form usually involves tone sandhi, a phonologically conditioned change in lexical tone. Two tone sandhi rules from Mandarin, the L tone sandhi rule and the MH tone sandhi rule, provide an illustration (from Chen, 2000: 20, 27).

Mandarin Chinese has four lexical tones: a high (H) tone, a mid-rising (MH) tone, a low (L) tone, and a high-falling (HL) tone. The L tone sandhi rule changes an L into an MH when the L precedes (i.e., occurs to the left of) another L. The MH tone sandhi rule changes a nonfinal MH into an H when it follows (i.e., occurs to the right of) by an H or an MH. In (3), the citation tones for 'to bury a horse' are MH and L, and their surface realizations are the same as their citation forms. In (4), the tone on the word 'buy' in 'to buy a horse' changes from citation L to sandhi MH following the L tone sandhi rule, making utterances (3) and (4) completely homophonous.

(3) mai 'to bury'
MH
mai ma *bury horse* 'to bury a horse'
MH L sandhi tones = citation tones

(4) mai 'to buy'
L
mai ma *buy horse* 'to buy a horse'
L L citation tones
MH L sandhi tones

(5)	fen	shui	ling	*divide water mountain-ridge* 'watershed'
	H	L	L	citation tones
	H	MH	L	sandhi tone forms (intermediate, nonrealized forms)
	H	H	L	sandhi tone forms (final surface forms)

In (5), the citation L tone on *shui* changes to an intermediate, nonrealized sandhi MH tone in accord with L tone sandhi, and that intermediate sandhi MH value for *shui* acts as input into the MH tone sandhi rule, changing the nonrealized sandhi MH tone to a final surface H tone. From these examples it is clear that the phonological shape of Chinese morphemes does undergo considerable variation, but such variation is entirely a function of phonological context.

To conclude, the reputation of Chinese as an isolating language is perhaps not so well-deserved if we rely merely on the monomorphemic word criterion, since the preponderance of Chinese words are multimorphemic. But if our criterion is how easy the morphemes of a language are to identify and individuate, then Chinese scores rather high on the isolating language scale.

Chinese Linguistic Tradition

G Casacchia, Università degli studi di Napoli 'L'Orientale,' Napoli, Italy

© 2006 Elsevier Ltd. All rights reserved.

In China, linguistic research started very early. Theoretical analysis, lexicography, and dialectology were cultivated by Chinese scholars before the foundation of the Empire (221 B.C.). On the other hand, some fields had to wait until they received a hint from foreign cultures. Phonology was born under the Indian influence in the 3rd century A.D., and grammatical studies began following some Western examples only in the 19th century.

The Beginnings

The idea that language is largely based on an agreement among human beings was established by Xunzi [Xunzi (Hsün-tzu) was one of the most outstanding Confucian philosophers and author of a book of the same name] and Moists [Moism is the doctrine founded by Mozi (Mo-tzu)]. According to the first, 'names are attached to things once for ever, but this link is based on an agreement,' and the latter added, 'names are like painted tigers' (i.e., just a pale image of the real thing).

With the foundation of the Empire, things changed. The major philosopher of the Han dynasty, Dong Zhongshu [Dong Zhongshu (Tung Chung-shu) played a key role in establishing Confucian orthodoxy], adopted the opposite idea of linguistic realism: A natural bond exists between names and things. The Han penchant toward the cosmological theory of the 'five elements' (everything in the world is connected with five principles and modifies following them) prevented them from a nominalistic theory of the language.

It is impossible to underevaluate the imprinting given by the ideographic writing system of Chinese on linguistic studies. The ideograms (it is well-known 'ideogram' is far from ideal when talking about Chinese characters, but more precise terms, such as sinograms or logograms, are not yet widely used), that nearly completely hide the phonological and morphological aspects of the language, and their importance as a tool of the state administration produced a sort of a 'pheticism of the ideograms' in the minds of the cultivated people, who seldom dared to see them closer or to 'open' them to better understand their nature. Therefore, since the very beginning, the pioneering linguistic works in China were not devoted to analyzing speech and its component, the word, but to collecting and comparing ideograms.

First, some dictionaries of difficult words appeared, including the *Ji jiu pian* ('Quick performances') and some others, among which the most important was the *Er Ya* ('Perfection attained'), a list of 2016 words

grammatical system threw a bright light over most of the specific features of Chinese.

Current Situation

Currently, all branches of linguistics are fully developed in China due to the efforts of many scholars at the international level, including Lü Shuxiang, Zhu Dexi, and many others.

The first stage, in the 1950s, was largely dominated by the influence of the Soviet Union.

For example, in a major debate over 'are there or are there not word classes in Chinese?' the core for a long time was actually 'are there or are there not in Chinese the same word classes as in Russian?'

However, it was also open to influences from the West such as structuralism. During the second stage, in the 1960s and 1970s, sociolinguistics (how to simplify the writing system and how to teach the national language) mainly held the ground. The third stage, after the opening to the world and the development of social sciences, succeeded in giving impulse to modern linguistics.

Nevertheless, the tradition still plays a role, and the strong points of Chinese linguistics remain paleography, etymology, dialectology, grammar, and lexicography – much more than general linguistics.

Chinese Lexicography

Li Ming, Soochow University, Suzhou, China

© 2006 Elsevier Ltd. All rights reserved.

A Brief Historical Survey

Lexicographical development in China can be divided into three stages. The rudimentary period followed a long and tortuous course from 200 B.C. to the 14th century. The inception of Chinese lexicography was closely related to the study of exegesis, critical interpretation of ancient texts, which inevitably involved the analyses of meaning. It is in this connection that some scholars regard 易经 (*Yi ching; The book of changes*) as the first dictionary in the Chinese language. However, the book hardly has any features typical of a modern dictionary.

It is generally agreed that 尔雅 (*Erya; Near correctness*), which came out in the Han Dynasty (206 B.C.–220 A.D.), consisting of 30 books about the accepted meanings of classic texts, was the earliest quasidictionary in China. The first Chinese dictionary in the modern sense of the word was 说文解字 (*Shuowen jiezi; The origin of Chinese characters*) by Xu Shen in the Eastern Han Dynasty (25–220 A.D.). The book contains some 10 000 Chinese characters with pronunciations and definitions. A few other books having characteristics of a dictionary or an encyclopedia in this stage paved the way for the advancement of Chinese lexicography, including books on Buddhism in the Tang Dynasty (618–907).

The intermediate phase (from 1368 to 1700) was marked by the compilation of the handwritten 永乐大典 (*Yongle dadian; The yongle canon*), a 60-volume encyclopedia compiled in 1408 in the Ming Dynasty (1368–1644). The most important lexicographical publications in this period are encyclopedic in nature, focusing on particular subjects. These include 本草纲目 (*Bencao gangmu; A compendium of herbal medicine*), 1578; 农政全书 (*Nongzheng quanshu; The encyclopedia of agriculture*), a 60-volume work published in 1639; 天工开物 (*Tiangong kaiwu; The exploitation of the works of nature*), a three-volume encyclopedia about agriculture and handicrafts published in 1637. The last of these was later translated into French, Japanese, German, and English.

The modern phase (from 1700 to the present) witnessed the publication in 1716 of a remarkable dictionary, 康熙字典 (*Kangxi zidian; The kangxi lexicon*), with 47 035 Chinese characters. Since then,

thousands of dictionaries have been produced, most of them being published after the 1900s. Some of the notable dictionaries are 四库全书 (*Siku quanshu; The complete library in four divisions*), compiled between 1772 and 1782; 中华大字典 (*Zhonghua da zidian; The great China character dictionary*), with 48 000 characters, compiled in 1915; 辞源 (*Ciyuan*), an encyclopedic dictionary with almost 100 thousand references, published in 1915; 国语正音字典 (*Guoyu zhengyin zidian; A Chinese character dictionary with revised pronunciations*), published in 1926; 新华字典 (*Xinhua zidian; Xinhua dictionary of Chinese characters*), published in 1957; 现代汉语词典 (*Xiandai hanyu cidian*; *A dictionary of modern Chinese*), published in 1978; 汉语大字典 (*Hanyu da zidian; An unabridged dictionary of Chinese characters*), published in 1988–1990; 汉语大词典 (*Hanyu da cidian; An unabridged Chinese dictionary*), compiled 1986–1993; and 中国大百科全书 (*Zhongguo da baike quanshu; The encyclopedia of China*), compiled 1980–1993. Robert Morrison published the first Chinese–English dictionary in 1815. A few other bilingual dictionaries came into being in the first two decades of the 20th century and this category grew in full swing from 1970 to the end of the century.

Recent Developments

Since the 1990s, a number of electronic dictionaries have been produced. Chinese dictionaries in the electronic media are chiefly focused on the 'personal digital assistant' (PDA) and other hand-held devices. There are a few online dictionaries and encyclopedias on CD-ROM, but they generally lack the multimedia functions that are the principal advantage of such dictionaries. For example, *The encyclopedia of China* has a four-CD version that is even larger in scope than Microsoft's *Encarta*. It boasts over 50 000 pictures. The other media formats (sounds, video clips, and animations), however, are yet to be incorporated. Pocket e-dictionaries in China have their own advantages, though. Most of them offer two-way translation and can be updated easily. As for online dictionaries, they invariably present a much more extensive vocabulary than is found in paper dictionaries, and are revised and updated at irregular intervals.

At one time, plagiarism was rampant, but after a celebrated lawsuit in 1993, Chinese copyright laws and intellectual property rights began to be respected. For several years, however, in the wake of this lawsuit, there were heated intellectual discussions in Chinese lexicographical circles about what constitutes a breach of copyright in dictionary-making and how to eliminate the problem.

Another significant development in Chinese lexicography has been a shift from prescriptivism to descriptivism. Take 现代汉语词典 (*A dictionary of modern Chinese*), for example. This dictionary used to be (and in many ways still is) considered as the authority on the Chinese language. It is a prescriptive model of how Chinese should be written. The new edition published in 1996, however, contains a number of colloquialisms and new borrowings from foreign languages.

In recent years, corpus linguistics has been given more attention in China. Quite a few corpora, ranging in size from 1 million to 70 million words, have been established in Guangzhou, Shanghai, Beijing, and Nanjing. For instance, the general-purpose Chinese corpus at Tsinghua University contains some 50 million words and the Chinese Academy of Social Sciences has a corpus with 10 million words. As a result, corpus-based dictionaries have been compiled and are available to the general public.

Retrieval Systems

In Chinese, the character is the basic semantic unit, so that conventionally the distinction can be made between 字典 (*zidian*), a dictionary of Chinese characters, and 词典 (*cidian*), a dictionary of Chinese words comprising one, two, or more characters. The generic term for dictionaries and encyclopedias in Chinese is 辞书 (*cishu*), which also denotes any reference work. Since Chinese is an ideographic writing system in which symbols represent ideas rather than sounds, the macrostructure of a Chinese dictionary is traditionally organized in brush-stroke order instead of the alphabetical order. The retrieval of characters in Chinese dictionaries is achieved by means of radicals. The user checks the radical index for the page number of the character to be consulted. Then, in the microstructure, the user looks for the word or words grouped under that character. The radicals are arranged in ascending order of the number of strokes. The basic rules for brush-stroke order are as follows: (1) horizontal strokes precede vertical strokes; (2) downward–left curved strokes go before downward–right curved strokes; (3) from top to bottom; (4) from left to right; (5) from outside to inside; (6) middle strokes go before strokes on the sides. Due to the complicated nature of Chinese characters, in 1997 the National Working Committee on Chinese Speech and Writing issued a set of guidelines called the Standard Brush-Stroke Order of Modern Chinese Characters.

In modern Chinese dictionaries, however, 拼音 (*pinyin*, a scheme for the Chinese phonetic alphabet in Roman letters), is adopted in addition to the radical index, so that the user can look up characters in the

alphabetical order of *pinyin*. As Chinese is a tonal language, the flat tone is conventionally given first for words having the same pronunciation but different tone, followed by the rising, falling-rising, and falling tones. In the case of homonyms, brush-stroke order applies.

In the 1920s, Wang Yunwu (Y. W. Wong), the editor-in-chief of the Commercial Press Ltd. in Shanghai, invented his 四角号码检字法 (*sijiao haoma jianzi fa*, the four corner system). Each Chinese character is given a four-digit number according to the brush strokes in the system. The user has to identify the elements of the four corners of the character in question by moving clockwise from the upper left-hand corner, then the upper right, next the lower left, and, finally, the lower right-hand corner. When the four digits have been determined, the user checks the four-corner index to find the page number for the character to be consulted. The system is difficult to handle at first, but once the rules are mastered it becomes easy. For various reasons, the four-corner system is out of fashion nowadays, at least in mainland China.

Standardization

The plethora of dialects in China makes it necessary to employ 普通话 (*putonghua*, or Mandarin) as the official language and to standardize the spoken and written forms. A number of academic organizations in China are directly or indirectly involved with language standardization, for example the National Working Committee on Chinese Speech and Writing, the National Committee on the Standardization of Chinese, the National Committee on the Standardization of Scientific and Technical Terminology, the Standardization Administration of China, the China Language Modernization Society, the China Language Society, and the China Lexicographical Society.

Three Chinese publishing houses specialize in dictionaries: Shanghai Lexicographical Publishing House, Hubei Lexicographical Publishing House, and Sichuan Lexicographical Publishing House. There used to be authoritarian control over which Chinese presses could publish reference works, but now such restrictions have been lifted. The Chinese journal 辞书研究 (*Cishu yanjiu, Lexicographical studies*) is devoted to issues related to all reference works.

Dictionary Types

Chinese lexicography in modern days covers every type in the field, ranging from desk dictionaries to pocket versions in size, from paper to electronic editions in media, and from monolingual to bilingual in language. Although written Chinese is homogeneous, the spoken form varies geographically. There are scores of such variations. To cope with this problem, and partly as an effort to preserve the cultural heritage, dictionaries have been compiled for the major regional dialects. It should be noted that 汉语 (*hanyu* Chinese or Mandarin), the official language in China, literally means 'a language spoken by the Han nationality.' There are other languages used by minority ethnic groups in the country, such as Tibetan, Mongolian, and Weiwuer. Bilingual dictionaries in China therefore may be foreign language (FL)-Chinese, Chinese-FL, minority language (ML)-Chinese, or Chinese-ML. In fact, many ML-Chinese and Chinese-ML dictionaries have been published since 1950.

Markets

Given the large population of China (1.29 billion in 2003), the market for dictionaries, both monolingual and bilingual, is vast and continues to expand. Over 400 million copies of 新华字典 (*Xinhua dictionary of Chinese characters*) have been printed between the first edition in 1953 and the 10th edition in 2004. Considering the fact that there are tens of millions of English learners in the country, it is not surprising that most bilingual dictionaries can command a ready sale. 新英汉词典 (*Xin yinghan cidian; A new English–Chinese dictionary*), for example, has sold over 10 million copies since the 1970s. International publishing houses have been trying to enter the market since China joined the World Trade Organization in 2001. It can be reasonably expected that, with the improvement of literacy among the young generation and the expansion of college enrollments, the dictionary market will grow even more extensively.

Chino, Eiichi (1932–2002)

J Tárnyiková, Palacky University, Olomouc, Czech Republic

© 2006 Elsevier Ltd. All rights reserved.

Eiichi Chino, who taught in the Tokyo University of Foreign Studies (Gaikokugo daigaku) and former president of Wakō University, was known above all as a Japanese Bohemicist, a specialist in Czech philology, who studied and later taught the Czech language, wrote textbooks (co-author of *Chekogo no nyūmon* [Introduction to the Czech language], 1976, Tokyo: Hakusuisha), lectured on Czech language and literature, and published a series of essays on various aspects of Czech cultural and political life (Chino, 1990, 1997). Eiichi Chino translated into Japanese a variety of text genres, ranging from books for children (cf. František Hrubín, *Kuřátko a obilí–Hiyoko to mugibatake* [The little chicken in a field of grain]) to film scripts (the Oscar nominated film *Kolya*), libretti (Leoš Janáček's opera *Osud – Unmei* [Fate]), and a collection of essays by the leading Czech structuralist Jan Mukařovský (co-translator, see Mukařovský, 1982). What brought Chino fame and admiration, however, were above all his translations of canonical Czech literature. He had a lifelong affection for Karel Čapek, whose unique style not only found in Chino a sensitive and creative interpreter (Karel Čapek's play 'R.U.R.' – *Robotto, Kareru Chapekku*. Tokyo: Iwanami Shoten, 1989) but also a keen director, who engaged his Tokyo students of Czech (at Gaikokugu daigaku) in staging the play. Preceding 'R.U.R.' were Chino's own essays on Karel Čapek (Chino, 1975). Chino wrote epilogues to many of his translations familiarizing Japanese readers with the Czech cultural setting. Among other Czech authors translated by Chino were Franz Kafka, Viktor Fischl, Milan Kundera (1992, 1998), and Ota Pavel (2000). In 2000, for rendering outstanding service to Czech culture (see also his articles and essays in *Asahi Shimbun* and a series of university lectures in the 1980s on the Prague Linguistic Circle), Eiichi Chino was awarded the Medal of Merit, First Grade by President Václav Havel. The interest in Czech philology, though deep and emotional, always remained part of Chino's broader interest in Slavic philology (including Old Church Slavonic, Russian, Polish, Slovak, Serbo-Croatian and Bulgarian), and comparative linguistics ("Studies of Non-Indo-European Languages" in Miyaoka, O. (ed.), *Languages of the North Pacific Rim: types and history*. 1992. Tokyo: Sanseidō,). Eiichi Chino was a co-editor of a 6-volume encyclopedia known as The Sanseidō encyclopaedia of linguistics (Chino, 1988–1996) and an author of many enlightening books on linguistics (Chino, 1980a, 1980b, 1994, 1999). These were preceded by studies on the Japanese language (Chino, 1977). Eiichi Chino's multifarious activities reflect the variety of his studies, completed at three universities: the Tokyo University of Foreign Studies (Russian), the University of Tokyo (general linguistics), and Charles University, Prague

(5)	fen	shui	ling	*divide water mountain-ridge* 'watershed'
	H	L	L	citation tones
	H	MH	L	sandhi tone forms (intermediate, nonrealized forms)
	H	H	L	sandhi tone forms (final surface forms)

In (5), the citation L tone on *shui* changes to an intermediate, nonrealized sandhi MH tone in accord with L tone sandhi, and that intermediate sandhi MH value for *shui* acts as input into the MH tone sandhi rule, changing the nonrealized sandhi MH tone to a final surface H tone. From these examples it is clear that the phonological shape of Chinese morphemes does undergo considerable variation, but such variation is entirely a function of phonological context.

To conclude, the reputation of Chinese as an isolating language is perhaps not so well-deserved if we rely merely on the monomorphemic word criterion, since the preponderance of Chinese words are multimorphemic. But if our criterion is how easy the morphemes of a language are to identify and individuate, then Chinese scores rather high on the isolating language scale.

Chinese Linguistic Tradition

G Casacchia, Università degli studi di Napoli 'L'Orientale,' Napoli, Italy

© 2006 Elsevier Ltd. All rights reserved.

In China, linguistic research started very early. Theoretical analysis, lexicography, and dialectology were cultivated by Chinese scholars before the foundation of the Empire (221 B.C.). On the other hand, some fields had to wait until they received a hint from foreign cultures. Phonology was born under the Indian influence in the 3rd century A.D., and grammatical studies began following some Western examples only in the 19th century.

The Beginnings

The idea that language is largely based on an agreement among human beings was established by Xunzi [Xunzi (Hsün-tzu) was one of the most outstanding Confucian philosophers and author of a book of the same name] and Moists [Moism is the doctrine founded by Mozi (Mo-tzu)]. According to the first, 'names are attached to things once for ever, but this link is based on an agreement,' and the latter added, 'names are like painted tigers' (i.e., just a pale image of the real thing).

With the foundation of the Empire, things changed. The major philosopher of the Han dynasty, Dong Zhongshu [Dong Zhongshu (Tung Chung-shu) played a key role in establishing Confucian orthodoxy], adopted the opposite idea of linguistic realism: A natural bond exists between names and things. The Han penchant toward the cosmological theory of the 'five elements' (everything in the world is connected with five principles and modifies following them) prevented them from a nominalistic theory of the language.

It is impossible to underevaluate the imprinting given by the ideographic writing system of Chinese on linguistic studies. The ideograms (it is well-known 'ideogram' is far from ideal when talking about Chinese characters, but more precise terms, such as sinograms or logograms, are not yet widely used), that nearly completely hide the phonological and morphological aspects of the language, and their importance as a tool of the state administration produced a sort of a 'pheticism of the ideograms' in the minds of the cultivated people, who seldom dared to see them closer or to 'open' them to better understand their nature. Therefore, since the very beginning, the pioneering linguistic works in China were not devoted to analyzing speech and its component, the word, but to collecting and comparing ideograms.

First, some dictionaries of difficult words appeared, including the *Ji jiu pian* ('Quick performances') and some others, among which the most important was the *Er Ya* ('Perfection attained'), a list of 2016 words

Figure 1 The 36 initial sounds divided into nine categories and printed on a hand as a memory aide. From *Qie yun zhi zhang tu* ('Tables to understand the rhymes') by Sima Guang, 10th century.

classified into 19 sections, without pronunciation, in the following way:

> *xu* (wait)/*si* (wait)/*ti* (stop)/*li* (reach)/*di* (attain)/*zhi* (stop)/*xi* (wait): They mean *dai* (wait).

The logic of the *Er Ya* was to list difficult words together with simpler ones in order to explain the first by the latter and to provide the writer with many synonyms. For this reason, this kind of lexicographical work had great success and approximately 150 similar books were compiled during the Empire, up to the past century.

The first dialectological works were clearly inspired by the *Er Ya*. The *Fang Yan* ('Local speeches') collected dialectal words together with more widespread words to attain the same results as *Er Ya*:

> *dang/xiao/zhe* mean *zhi* (know). In Chu they say *dang* or *xiao*, and between Qi and Song they say *zhe*.

In the book, the key notion of 'common speech' is found for the first time, as a reflection of the unified Empire in the minds of its inhabitants.

However, the main work of Han dynasty linguistics is another dictionary, the *Shuo wen jie zi* ['Explanation of words'; *wen* refers to the simple ideograms (e.g., 'tree') and *zi* to the complex ideograms (e.g., 'forest' – made of two trees to suggest plurality); *shuo* means 'explain' and *jie* 'dissect' or 'analyze'], written by Xu Shen between 100 and 121 A.D. With nearly 10 000 monosyllabic words, it is a huge work, but its importance is in its several lexicographic inventions, so apt to the description of Chinese language, that have lasted up to the present.

First, all of the ideograms are divided into six categories: pictograms, symbols, associated logic elements, associated semio- and phono-elements, and two less important categories. The definition is highly standardized. For instance, the first category is explained as 'x mean y. Pictogram,' the third as 'x mean y. From a, from b,' and the fourth as 'x mean y. from a, sounds as b.'

> *Ming niao sheng ye. Cong niao, cong kou*
> *Ming* (sing of a bird) means voice of a bird. From *niao* 'bird,' from *kou* 'mouth.'

> *Bing ming ye. Cong huo, bing sheng*
> *Bing* (bright) means bright. From *huo* 'fire,' sounds as *bing*.

Furthermore, for the first time the pronunciation of the items is also given by an homophonus ideogram, and the formula *x du ruo y* 'x is read as y.'

Moreover, a list of 540 graphic components was established, also for the first time (e.g., wood, water, word, ship, worm, and roof), in order to classify all the 10 000 graphs of the texts. These graphic components, reduced during the last dynasty to 214 [in *Kangxi zidian*, 'Dictionary of the emperor Kangxi (K'ang-hsi),' by Zhang Yushu, 1716], are still used in the dictionaries of today under the name 'radicals.'

Besides the previously mentioned works, based on solid scientific grounds, the realistic tradition of the Han produced some lexicographical works also worth mentioning. The best among them is the *Shi ming* ('Names explained') by Liu Xi:

> *Jing* ('view') means *jing* ('territory'): what eyes embrace within a certain territory.
> *Jin* ('brocade') means *jin* ('gold'): what is as precious as gold.

The theoretical basis of the work was the so-called *sheng xun* ('phonological exegesis'), according to which any definitions must be based on synonymy and homophony.

The Flourishing Age

The contacts with Sanscrit, due to the introduction of Buddhism in China from the 1st century A.D., finally gave the Chinese the suggestion to split the ideograms into two parts in order to start a phonological analysis of their own language and to establish a better way of writing their readings.

Sun Yan (a scholar, fl. during the Wei dynasty, 220–265) was likely the first in his *Er Ya yin yi* ('Sounds and meanings in *Er Ya*') to adopt a new system called *fanqie* (lit. 'rotate and cut') to analyze phonologically the words in *Er Ya*. The *fanqie* system is one of the most outstanding achievements of the old linguistics. According to it, the reading of an ideogram is given through two other ideograms with no connection in meaning, the first giving the reading

Figure 2 A rhyme book, *Yunjing* ('A mirror of rhymes'), by Zhang Lizhi (1161). The column at the top provides the initial sounds. The four columns below the first provide the final sounds, divided according to the 'tones' (the four black circles) and the 'degrees' (/-a-/, /-u-/, /-i-/, and /-y-/).

of the initial sound (*sheng*), and the second giving the reading of the final sound (*yun*):

dong = *d(u)* + *(h)ong*
dong (east) = *d(u)* (capital) + *(h)ong* (red)

This system was not only a brilliant invention for an ideographic writing system but also very productive and gave birth to a new branch of research, covering the whole length of the Empire and that lasted until the last century.

First, the *yun shu* ('books of rhymes'), a large number of dictionaries arranged phonologically and grouping together those words sharing the same final sound, were written, mainly to help students during the imperial exams (in which one of the most important tests was writing poems) but also to give a new impulse to linguistics. The first book of rhymes was *Qie Yun* ('Rhymes according the *fanqie*') by Lu Fayan, written in 601 A.D.

Second, grouping together the words sharing the same initial sound, Chinese derived 36 words working as the letters of the Latin alphabet: *kiem* (see) for /k-/, *k'i* (creek) for /k'-/, and so on. From a technical standpoint, the time was ripe to adopt a more rational system of writing than the ideographic one. Nevertheless, a reform that could have given an alphabet to Chinese was never undertaken, for the good reason that a highly complicated system was one of the *raisons d'etre* of the powerful officers who ruled the Empire.

Third, not only the initial sounds but also the final sounds were identified and classified with slightly more than 100 ideograms distributed into four 'degrees' according to the openeness of the first syllable: /-a-/ ('open mouth degree') as in *ma* (horse), /-u-/ ('close mouth degree') as in *hu* (lake), /-i-/ ('teeth at the same level degree') as in *di* (earth), and /-y-/ ('round mouth degree') as in *lü* (donkey).

As a dignified conclusion to the classical linguistics period, in 1899 some casual discoveries gave birth to modern paleography. A huge amount of 'dragon bones' (which were at first called *jiaguwen*, 'oracle bones') with inscriptions dating back to 1500 B.C., completely renewed the traditional ideas of paleography and etymology, based for all the extent of the Empire on more recent graphs.

For instance, for centuries the character for *wang* ('king'), was considered 'a trait d'union between heaven, earth and man,' although it is simply the picture of an axe plunged into the ground.

The study of *jiaguwen* is a developing science; to date, not more than approximately 60% of the old inscriptions have been deciphered.

The Reform

The 20th century saw the birth of one more linguistic branch: grammar and syntax. The clashes and contacts with the West persuaded the Chinese that learning Western sciences was fundamental to saving

Figure 3 One page of the *Kang xi zi dien* ('A dictionary of the emperor Kangxi'). Out of the frame are the words in the old writing system called *xiao zhuan* ('small seal'). Within the page, the words are followed by the definitions and the sources quoted (in the circles).

and developing the country, and the idea arose to spare much of the time devoted to traditional learning by heart of the thousands of Chinese characters through Western techniques (i.e., grammar and syntax, mainly English, but also Latin and French) and so to be able to study more natural sciences and engineering.

In 1898, the first grammar of classical Chinese, *Ma shi wen tong* ('A grammar by dr Ma') by Ma Jianzhong was published, followed in 1921 by the first grammar of modern Chinese, *Xinzhu guoyu wenfa* ('A new grammar of national language') by Li Jinxi.

In the past, no systematic description of the language could be found, besides some general ideas such as the distinction between *shizi* ('full') and *xuzi* ('empty words') or some research on particles. Later, many comprehensive grammars were brought to life, which despite their heavy debt to the Western

grammatical system threw a bright light over most of the specific features of Chinese.

Current Situation

Currently, all branches of linguistics are fully developed in China due to the efforts of many scholars at the international level, including Lü Shuxiang, Zhu Dexi, and many others.

The first stage, in the 1950s, was largely dominated by the influence of the Soviet Union.

For example, in a major debate over 'are there or are there not word classes in Chinese?' the core for a long time was actually 'are there or are there not in Chinese the same word classes as in Russian?'

However, it was also open to influences from the West such as structuralism. During the second stage, in the 1960s and 1970s, sociolinguistics (how to simplify the writing system and how to teach the national language) mainly held the ground. The third stage, after the opening to the world and the development of social sciences, succeeded in giving impulse to modern linguistics.

Nevertheless, the tradition still plays a role, and the strong points of Chinese linguistics remain paleography, etymology, dialectology, grammar, and lexicography – much more than general linguistics.

Chinese Lexicography

Li Ming, Soochow University, Suzhou, China

© 2006 Elsevier Ltd. All rights reserved.

A Brief Historical Survey

Lexicographical development in China can be divided into three stages. The rudimentary period followed a long and tortuous course from 200 B.C. to the 14th century. The inception of Chinese lexicography was closely related to the study of exegesis, critical interpretation of ancient texts, which inevitably involved the analyses of meaning. It is in this connection that some scholars regard 易经 (*Yi ching; The book of changes*) as the first dictionary in the Chinese language. However, the book hardly has any features typical of a modern dictionary.

It is generally agreed that 尔雅 (*Erya; Near correctness*), which came out in the Han Dynasty (206 B.C.–220 A.D.), consisting of 30 books about the accepted meanings of classic texts, was the earliest quasidictionary in China. The first Chinese dictionary in the modern sense of the word was 说文解字 (*Shuowen jiezi; The origin of Chinese characters*) by Xu Shen in the Eastern Han Dynasty (25–220 A.D.). The book contains some 10 000 Chinese characters with pronunciations and definitions. A few other books having characteristics of a dictionary or an encyclopedia in this stage paved the way for the advancement of Chinese lexicography, including books on Buddhism in the Tang Dynasty (618–907).

The intermediate phase (from 1368 to 1700) was marked by the compilation of the handwritten 永乐大典 (*Yongle dadian; The yongle canon*), a 60-volume encyclopedia compiled in 1408 in the Ming Dynasty (1368–1644). The most important lexicographical publications in this period are encyclopedic in nature, focusing on particular subjects. These include 本草纲目 (*Bencao gangmu; A compendium of herbal medicine*), 1578; 农政全书 (*Nongzheng quanshu; The encyclopedia of agriculture*), a 60-volume work published in 1639; 天工开物 (*Tiangong kaiwu; The exploitation of the works of nature*), a three-volume encyclopedia about agriculture and handicrafts published in 1637. The last of these was later translated into French, Japanese, German, and English.

The modern phase (from 1700 to the present) witnessed the publication in 1716 of a remarkable dictionary, 康熙字典 (*Kangxi zidian; The kangxi lexicon*), with 47 035 Chinese characters. Since then,

Chino, Eiichi (1932–2002)

J Tárnyiková, Palacky University, Olomouc, Czech Republic

© 2006 Elsevier Ltd. All rights reserved.

Eiichi Chino, who taught in the Tokyo University of Foreign Studies (Gaikokugo daigaku) and former president of Wakō University, was known above all as a Japanese Bohemicist, a specialist in Czech philology, who studied and later taught the Czech language, wrote textbooks (co-author of *Chekogo no nyūmon* [Introduction to the Czech language], 1976, Tokyo: Hakusuisha), lectured on Czech language and literature, and published a series of essays on various aspects of Czech cultural and political life (Chino, 1990, 1997). Eiichi Chino translated into Japanese a variety of text genres, ranging from books for children (cf. František Hrubín, *Kuřátko a obilí–Hiyoko to mugibatake* [The little chicken in a field of grain]) to film scripts (the Oscar nominated film *Kolya*), libretti (Leoš Janáček's opera *Osud – Unmei* [Fate]), and a collection of essays by the leading Czech structuralist Jan Mukařovský (co-translator, see Mukařovský, 1982). What brought Chino fame and admiration, however, were above all his translations of canonical Czech literature. He had a lifelong affection for Karel Čapek, whose unique style not only found in Chino a sensitive and creative interpreter (Karel Čapek's play 'R.U.R.' – *Robotto, Kareru Chapekku.* Tokyo: Iwanami Shoten, 1989) but also a keen director, who engaged his Tokyo students of Czech (at Gaikokugu daigaku) in staging the play. Preceding 'R.U.R.' were Chino's own essays on Karel Čapek (Chino, 1975). Chino wrote epilogues to many of his translations familiarizing Japanese readers with the Czech cultural setting. Among other Czech authors translated by Chino were Franz Kafka, Viktor Fischl, Milan Kundera (1992, 1998), and Ota Pavel (2000). In 2000, for rendering outstanding service to Czech culture (see also his articles and essays in *Asahi Shimbun* and a series of university lectures in the 1980s on the Prague Linguistic Circle), Eiichi Chino was awarded the Medal of Merit, First Grade by President Václav Havel. The interest in Czech philology, though deep and emotional, always remained part of Chino's broader interest in Slavic philology (including Old Church Slavonic, Russian, Polish, Slovak, Serbo-Croatian and Bulgarian), and comparative linguistics ("Studies of Non-Indo-European Languages" in Miyaoka, O. (ed.), *Languages of the North Pacific Rim: types and history.* 1992. Tokyo: Sanseidō,). Eiichi Chino was a co-editor of a 6-volume encyclopedia known as The Sanseidō encyclopaedia of linguistics (Chino, 1988–1996) and an author of many enlightening books on linguistics (Chino, 1980a, 1980b, 1994, 1999). These were preceded by studies on the Japanese language (Chino, 1977). Eiichi Chino's multifarious activities reflect the variety of his studies, completed at three universities: the Tokyo University of Foreign Studies (Russian), the University of Tokyo (general linguistics), and Charles University, Prague

(Slavic philology, Czech and general linguistics). As a professor of Wakō University, Chino wrote an essay entitled 'Japanese – a treasure trove.' (*Nihongo Kyoiku Tsushin, 16*). The title is symbolic: Eiichi Chino's legacy is a treasure trove of many and varied contributions to linguistics, literature, foreign language teaching (Chino, 1986), and translatology – and a challenge for those interested in this charismatic polyglot and his research (cf. the obituary by Vlasta Winkelhöferová (2002) 'Odešel japonský bohemista Eiiči Čino.' *Dokořán 22, Obec Spisovatelů.* [Bulletin of the union of writers.] Prague).

Chiri, Mashiho (1909–1961)

A Pérez Pereiro, Arizona State University, Tempe, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Mashiho Chiri was the first ethnic Ainu person to attend Tokyo Imperial University and was hailed as the Ainu genius, countering claims of Ainu inferiority to the Japanese. He was born in Hokkaido, Japan, in 1909 to an Ainu family and grew up in the town of Muroran. Despite his Ainu heritage, the stigma associated with the Ainu language and culture at the time being what it was, he did not grow up speaking Ainu, but Japanese instead. He remarked that he would later have to learn Ainu as a foreign language, as he might French or German (German, Standard), and that this pained him greatly.

Chiri's aunt, Matsu Kannari, and his sister, Yukie Chiri, were Ainu speakers and informants of Kyosuke Kindaichi, the famous Ainu scholar. Kindaichi encouraged Mashiho to study and helped him enter a prestigious high school and, later, Tokyo Imperial University. Initially, Chiri entered the English literature department, but later transferred to the department of linguistics where Kindaichi was teaching at the time. Together with Kindaichi, he published his dissertation *Ainu goho gaisetsu,* where he provided a description of Ainu grammar.

Chiri and Kindaichi had different interests with regard to their studies. While Kindaichi was primarily interested in the classical language of the epic yukar, Chiri, although also a scholar of the yukar, chose to focus on the colloquial varieties of the spoken

(Slavic philology, Czech and general linguistics). As a professor of Wakō University, Chino wrote an essay entitled 'Japanese – a treasure trove.' (*Nihongo Kyoiku Tsushin, 16*). The title is symbolic: Eiichi Chino's legacy is a treasure trove of many and varied contributions to linguistics, literature, foreign language teaching (Chino, 1986), and translatology – and a challenge for those interested in this charismatic polyglot and his research (cf. the obituary by Vlasta Winkelhöferová (2002) 'Odešel japonský bohemista Eiiči Čino.' *Dokořán 22, Obec Spisovatelů.* [Bulletin of the union of writers.] Prague).

Chiri, Mashiho (1909–1961)

A Pérez Pereiro, Arizona State University, Tempe, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

Mashiho Chiri was the first ethnic Ainu person to attend Tokyo Imperial University and was hailed as the Ainu genius, countering claims of Ainu inferiority to the Japanese. He was born in Hokkaido, Japan, in 1909 to an Ainu family and grew up in the town of Muroran. Despite his Ainu heritage, the stigma associated with the Ainu language and culture at the time being what it was, he did not grow up speaking Ainu, but Japanese instead. He remarked that he would later have to learn Ainu as a foreign language, as he might French or German (German, Standard), and that this pained him greatly.

Chiri's aunt, Matsu Kannari, and his sister, Yukie Chiri, were Ainu speakers and informants of Kyosuke Kindaichi, the famous Ainu scholar. Kindaichi encouraged Mashiho to study and helped him enter a prestigious high school and, later, Tokyo Imperial University. Initially, Chiri entered the English literature department, but later transferred to the department of linguistics where Kindaichi was teaching at the time. Together with Kindaichi, he published his dissertation *Ainu goho gaisetsu,* where he provided a description of Ainu grammar.

Chiri and Kindaichi had different interests with regard to their studies. While Kindaichi was primarily interested in the classical language of the epic yukar, Chiri, although also a scholar of the yukar, chose to focus on the colloquial varieties of the spoken

language. After graduation, Chiri started teaching in Sakhalin, then a Japanese territory, and began studying the Sakhalin dialect of Ainu. The result was *Ainu goho kenkyu*, a grammar of this dialect. He was convinced of the importance of distinguishing between the different dialects and using them to understand the local culture where each dialect was spoken. He also made significant contributions to the study of geographical names, sometimes in collaboration with Hidezo Yamada, a renowned scholar of Ainu place names. In the course of his studies, Chiri also proposed that Ainu, still believed to be a language isolate, exhibits vowel harmony, a property associated with the Altaic languages.

Chiri resented the subordination of the Ainu in Japan and the discrimination which they endured. He himself was also teased at school, being called 'inu' or dog, a common slur against the Ainu. He was also critical, perhaps excessively so, of what he considered to be 'bad scholarship' on the Ainu people. Although he was raised in a Japanized home, he sometimes claimed that non-Ainu scholars, especially those with whom he disagreed, did not understand the language and culture the way he did. In particular, he attacked John Batchelor and his famous dictionary, referring to it as a collection of errors. Chiri began what would be his own magnum opus, the *Classified Ainu dictionary*, a complete dictionary of the Ainu language accounting for dialectical variations. In June of 1961, at the age of 52, Mashiho Chiri died after having written only three of the planned ten volumes.

Present Indians of Western Colombia

Colombia, a basically Spanish-speaking nation in the northwestern corner of South America, conserves a considerable number of Indian languages. The speakers of the various languages survived the colonization of the subcontinent, isolating themselves in rather desolate places far from the urban centers, where there were no mestizos and only the black population dared to enter. Of the immense mosaic of aboriginal languages thought to have existed when the Europeans arrived in what is today Colombian territory – for its privileged situation as a crossroads for peoples from north to south and from south to north of the continent – about 90 peoples still survive. They are characterized as different from the majority of the Spanish-speaking population, because they maintain particular sociocultural characteristics, among them a language of their own, as is the case for 65 of these 90 peoples. These languages have been characterized by the most diverse range of linguistic varieties, i.e., isolating, agglutinating, and flexive languages, as correspond to such highly varied regions in which their speakers are found: desert zones, grasslands, jungles, coastal littorals, river littorals, foothills, and mountainous zones of both temperate and cold climates.

Four of these Indian languages still survive in western Colombia, which correspond to four ethnic groups that continue to preserve their own cultural characteristics, such as their language and, therefore, their particular way of thinking, or worldview. The first of these four languages is Tule, of the Chibchan linguistic family, the speakers of which are known as 'Cunas.' They occupy the extreme northwestern part of the country, in the Golfo de Uraba (where there are no more than 1000 individuals) and the majority are found in the neighboring country of Panama, in the San Blas Islands (around 40 000 individuals), where they have immigrated for more than half a century. The second language is Awa or Awa-Cuaiquer,

language. After graduation, Chiri started teaching in Sakhalin, then a Japanese territory, and began studying the Sakhalin dialect of Ainu. The result was *Ainu goho kenkyu*, a grammar of this dialect. He was convinced of the importance of distinguishing between the different dialects and using them to understand the local culture where each dialect was spoken. He also made significant contributions to the study of geographical names, sometimes in collaboration with Hidezo Yamada, a renowned scholar of Ainu place names. In the course of his studies, Chiri also proposed that Ainu, still believed to be a language isolate, exhibits vowel harmony, a property associated with the Altaic languages.

Chiri resented the subordination of the Ainu in Japan and the discrimination which they endured. He himself was also teased at school, being called 'inu' or dog, a common slur against the Ainu. He was also critical, perhaps excessively so, of what he considered to be 'bad scholarship' on the Ainu people. Although he was raised in a Japanized home, he sometimes claimed that non-Ainu scholars, especially those with whom he disagreed, did not understand the language and culture the way he did. In particular, he attacked John Batchelor and his famous dictionary, referring to it as a collection of errors. Chiri began what would be his own magnum opus, the *Classified Ainu dictionary*, a complete dictionary of the Ainu language accounting for dialectical variations. In June of 1961, at the age of 52, Mashiho Chiri died after having written only three of the planned ten volumes.

Present Indians of Western Colombia

Colombia, a basically Spanish-speaking nation in the northwestern corner of South America, conserves a considerable number of Indian languages. The speakers of the various languages survived the colonization of the subcontinent, isolating themselves in rather desolate places far from the urban centers, where there were no mestizos and only the black population dared to enter. Of the immense mosaic of aboriginal languages thought to have existed when the Europeans arrived in what is today Colombian territory – for its privileged situation as a crossroads for peoples from north to south and from south to north of the continent – about 90 peoples still survive. They are characterized as different from the majority of the Spanish-speaking population, because they maintain particular sociocultural characteristics, among them a language of their own, as is the case for 65 of these 90 peoples. These languages have been characterized by the most diverse range of linguistic varieties, i.e., isolating, agglutinating, and flexive languages, as correspond to such highly varied regions in which their speakers are found: desert zones, grasslands, jungles, coastal littorals, river littorals, foothills, and mountainous zones of both temperate and cold climates.

Four of these Indian languages still survive in western Colombia, which correspond to four ethnic groups that continue to preserve their own cultural characteristics, such as their language and, therefore, their particular way of thinking, or worldview. The first of these four languages is Tule, of the Chibchan linguistic family, the speakers of which are known as 'Cunas.' They occupy the extreme northwestern part of the country, in the Golfo de Uraba (where there are no more than 1000 individuals) and the majority are found in the neighboring country of Panama, in the San Blas Islands (around 40 000 individuals), where they have immigrated for more than half a century. The second language is Awa or Awa-Cuaiquer,

classified as an independent language, whose speakers are thought to number about 4000 and are located in the extreme southwestern part of the country (in the department of Nariño) and in smaller numbers in the neighboring country of Ecuador. The third and fourth languages are Waunméu (Woun Meu) and Embera, which belong to the so-called Choco language group, which has only recently been classified as an independent linguistic family.

Waunméu is spoken by the Waunanas, who number around 4000 individuals in Colombia, along the lower San Juan River, in the south of the department of Choco, and no more than 2000 individuals who have immigrated to the Province of Darien, in Panama. Embera is spoken by the Indians who call themselves Emberas but who are known by different names in the literature because they constitute a much larger number of speakers – around 60 000 – divided in various dialects. The Emberas are dispersed throughout the western part of Colombia and even in the frontier zones of Panama and Ecuador, and some of these dialects have grown so far apart that they are now mutually unintelligible.

Of course, this is a timid sample of the much greater number of ethnic groups that inhabited the western part of Colombia when the Europeans arrived, among which we can recall the names of the Idabáez, Ingarás, Birus, Surrucos, Poromeas, and the present-day Kunas, Waunanas, Katíos, or Emberas. Some of the denominations applied to the Indians then generally known as 'Choco' or 'Chocoes' were the Andáguedas, Baudó, Chamís, Dabeibas, Dariens, Katíos, Noanamás, and Saijas. Nowadays it is known that these names are derived from the names of the regions inhabited by these groups, which generally took the name of the main river that crossed through their territory and, in the case of the name 'Katío,' to the fact that the Embera Indians eventually occupied the region of the Katío Indians, a brave warrior tribe that succumbed to the Spanish.

The Embera Indians occupy a much greater territory today than they did at the time of the arrival of the Europeans, but with a very atomized coverage, i.e., only in different and specific points of little extension. Mestizo settlers displaced them to these Indian reservations, called 'Resguardos' or 'Cabildos,' which were very effective in the colonial period in preventing the extinction of these peoples, by impeding their occupation by outsiders but obliging the Emberas to give up the extensive territories in which they had once freely roamed.

In this article we see the different dialects into which the Embera language is presently divided. These dialects are a product of the different regions in which the Embera Indians have settled since the arrival of the Spanish, in different latitudes of the continent but always limited to a fringe that extends from the western littoral: the Pacific coast of Colombia, from north to south, to the Cauca River, which separates the western and central cordilleras stretching from north to south along the country, together with the eastern cordillera, the final branches of which disappear as they enter the Caribbean region of Colombia. Thus, the scenario that the Choco Indians occupy consists of the Pacific coast of Colombia, with its jungle plains; the Province of Darién, in Panama; and the spurs of the western cordillera and its terminal branches to the west of the Cauca River.

Retrospective of Linguistic Studies and Attempts to Classify the Emberas

The inclusion within a single linguistic family of the speech of the different Choco groups (the Waunana language and the different Embera dialects) that survived the Conquest and the colonial period is a recent fact. Their classification within any one of the great variety of American linguistic families is still open to discussion.

In the literature on the country's Indians, there is abundant documentation on population and migrations of the Choco, from chroniclers like Fray Pedro Simón, Bartolomé de Las Casas, Jorge Robledo, Juan de Castellanos, Pedro Cieza de León, to recent researchers like Henry Wassen, Katleen Romoli, Reina Torres de Arauz, Sven Isacsson, Mauricio Pardo, and Patricia Vargas. The last two, who are Colombian authors, have advanced in research about the Emberas, having reviewed all previous studies. In his article 'Bibliografía sobre indígenas Choco' (1981), for example, Pardo did an excellent review of the ethnohistoric literature available to date, and in 'Regionalización de indígenas Choco' (1987), he updated the discussion of the ethnohistoric panorama. Vargas (1986), on the other hand, found that the incursion of the Emberas into the territories of the Katío Indians did not mean the total extinction of the latter, because the two peoples intermingled, which is why the present Emberas of the region present particular characteristics that could be assigned to the Katíos.

The term Choco was already used in the 17th century to designate the Emberas of the upper San Juan and Atrato rivers and the Waunanas of the lower San Juan River. The earliest report known about the Emberas is found in the diary of the missionary Father Joseph Palacios de la Vega, around 1787, in San Cipriano, on the San Jorge River. This linguistic material, consisting of 37 phrases and 107 morphemes, fundamentally corresponds to the speech of the present Emberas of the northeast (Reichel-Dolmatoff, 1955).

A series of vocabularies was later collected by travelers, mostly foreigners, in different Choco Indian localities (Mollien, 1824; Cullen, 1851; Seeman, 1851; Bastian, 1876; Greiffenstein, 1878; Collins, 1879; White, 1884; Peláez, 1885; Etiene, 1887; Simons, 1887; Pinart, 1887; Velásquez, 1916; Robledo, 1922). These materials fundamentally served as the basis for analysis and classification until the middle of the 20th century.

But there have also been comparative studies since the 19th century: Bollaert (1860) proposed affinities between the Choco and Mesoamerican groups; Adam (1888) compared vocabularies obtained by Cullen, Seeman, and Uribe; Brinton (1891) observed the territorial extension of the speech of the Choco; Chamberlain (1907) determined that the geographical limits of the Choco were between 8 and 4 degrees northern latitude, between the Golfo de Urabá and the Golfo de San Miguel, and proposes Choco as an independent linguistic group; Lehmann (1910, 1920) suggested kinship with the Chibcha dialects of the Barbacoas and Talamanca groups; Loukotka (1968 [1942]) reaffirmed the separation of these languages as an independent linguistic family and recognized nine extant languages and five extinct languages; Rivet (1912, 1924, 1943) compared elements of the Choco vocabulary with 56 Caribe dialects, 34 Chibcha dialects, and 29 Arawak dialects and concluded that there was a strong Caribe influence and, to a much lesser degree, Chibcha and Arawak influence; Ortiz (1937, 1940, 1954, 1965), Mason (1950), Meillet and Cohen (1952), and Tovar (1961) followed Loukotka's regionalization and Rivet's affiliation.

The first attempts to classify the native languages of America were made in the second half of the 20th century. At the beginning of the 20th century, 19 independent language families were mentioned for the Pacific coast, including the Choco family (see, for example, the classifications of Alexander Chamberlain [1913] for the linguistic families of South America). Later researchers, such as Paul Rivet (1944), reduced this number and proposed the inclusion of the Choco family within other macrofamilies, like the Chibcha or the Caribe. At present, in light of recent linguistic explorations, the thesis of the independence of this family seems to be the most reliable, vindicating its defenders, among whom, in addition to Chamberlain, we can name Nordenskiold (1928), Loukotka (1968 [1942]), Tovar and Larrucea (1984), and Pardo and Aguirre (1993).

The cultural unity and the common origin of the Choco Indians were the subject of controversy for a long time. Mason's classification (1950) (broadened with that of Greenberg, 1960), for example, divided the Choco languages into Empera, with 3 variants; Catío (Embera-Catío), with 14 variants; and Noanamá (with 1 variant). Loukotka (1968 [1942]) had already spoken of 9 extant and 5 extinct Choco languages, and later Loukotka and Rivet proposed 10 extant variants for the Choco group (which they call the Emperá division) and 2 extinct ones (see Ortiz, 1965: 197–200).

Jacob Loewen (1960) confirmed Erland Nordenskiold's statement, testifying that linguistically only two languages (Waunana and Embera) – mutually unintelligible but nonetheless related – belonged within the Choco family, and proposed, with a phonological criterion, four large dialectal areas, one Waunana and three Embera, with lexical variations within the Embera areas.

Among the main bibliographical compilations on the Choco languages were those of Adam (1888), with 7 references; Lehmann (1920), with 30 references; Reichel-Dolmatoff (1945), with 38 references; Ortiz (1954), with 60 references; Loewen (1963), with 191 references, which were not only linguistic but historical as well; Ortega (1978), with 67 references; and Pardo (1981), with 72 references, and (1986), a survey of everything written on the subject to date, with 135 references, including everything from academic studies to simple lists of words.

There have been grammatical studies of the Embera language since 1881, when José Vicente Uribe published a brief article in which he presented the different types of Embera words in a general way. In 1936, Fray Pablo del Santísimo Sacramento published a grammatical essay on the speech of the Embera-Catíos of the Apostolic Prefecture of Urabá, as well as a classification of Embera, in which he dedicated a small portion to the syntax of the language. In 1918, an anonymous Catío-Spanish catechism appeared for missionaries of Antioquia. There is also an undated Catía grammar by María Betania (quoted in Pinto, 1974), and the Claretian priest Constancio Pinto published a Catío-Español dictionary (1950), as well as another extensive dictionary with grammar (1974).

Scientific studies based on fieldwork began with the research of Jacob Loewen, an American Mennonite missionary who did a study for a master's degree (1954) among the Waunana Indians of the lower San Juan River, and a doctoral thesis (1958) on the speech of the Emberas of the Sambú River, in the province of Darién in Panama. Loewen also wrote numerous articles on Embera phonology and dialectology, on comments on traditional stories, on loans from Spanish, on problems of bilingual literacy programs, and on basic readers in Indian languages.

Jean Caudmont (1955) elaborated notes on phonological and grammatical generalities through the use of field notes of Reichel-Dolmatoff (1945), taken 10 years earlier among the Embera group in Riofrío

in the department of Valle, who had emigrated from the region of the Chamí. The Claretian missionary Constancio Pinto, who lived with the Emberas of the region of the Chamí (headwaters of the San Juan River) for more than 40 years, published a dictionary (1950) of the Embera language, as well as a book with a much more extensive vocabulary and with a section on grammar (1974). Despite their having been based on methodical fieldwork, these studies suffered from the fact that they had been transcribed using Spanish-language phonetics and indistinctly presented, especially in the work of Pinto, words from zones like the Chamí, the Andágueda, the Sinú, and the Atrato, without taking the dialectal variations into account. With more linguistic precision, the Swedish researcher Nils Holmer (1963), in one of the publications of the Gutemburg Ethnographic Museum, occupied himself extensively with phonological and morphological aspects of Waunana.

The Summer Institute of Linguistics (SIL), which arrived in the country in 1962, carried out linguistic studies in distinct zones inhabited by Embera Indians. Francés Gralow (1976) elaborated a phonological description for the Chamí zone. In the 1970s, Eileen Rex and Mareike Schotlenndreyer traveled throughout the municipalities of Dabeiba, Frontino, and Chigorodó, in the department of Antioquia, and the upper Sinú, in the department of Córdoba, and published a phonology (1973) of the speech of the Emberas of the upper Sinú and northwestern Antioquia. Schotlenndreyer developed a literacy primer for the zone of Chigorodó (1973) and a structural analysis of her and Rex's stories (1977). Eileen Rex wrote her master's thesis on the Catía grammar (1975). Phillip Harms developed basic readers on the Embera language and tales and stories in the company of the natives from 1981 to 1985, for the Emberas of the Saija River on the coast of the department of Cauca, to the south of the department of Choco, and carried out a phonological description with Judy Powell (1984) and a grammatical study of the speech of these Emberas (Harms, 1987). Powell also mimeographed some Embera stories and biblical passages. David Stansell, who lived for more than 10 years among the Emberas of the Bojayá River in the department of Choco, wrote about them in *Aspectos de la cultura material de grupos étnicos de Colombia* (1973). Michael and Nellis (1984) produced primers in Chamí for the Emberas of the Valle de Garrapatas in the department of Valle del Cauca.

Gordon Horton worked with the Emberas of the upper Sinú in the 1960s and 1970s, mainly on the morphology of the language, and developed a series of primers and other didactic materials. Miguel Loboguerrero carried out a linguistic study (1976) on the dialect of the Chamí region; his resulting work included a phonological description, a grammatical description, and a corresponding lexicon. Nelly Mercedes Prado did an analysis of the 'Epera' variant ('Embera,' according to the phonology of this dialect) of the Saija River (1982) as her master's thesis, the presentation of which included phonology, morphology, and an appendix titled 'Un estudio inicial,' along with a lexicon of 845 items, each with its respective phonetic transcription. She continued her work with the publication of didactic materials (1985), further explored aspects of the language, such as nasality (1991), and later worked in ethnolinguistic conflicts between blacks and Indians (1992) within the broadest project, known as 'Cada río tiene su decir.'

Many missionaries working in Embera territories have concerned themselves with the language. One primer on the language of the Emberas of the upper San Juan, with an alphabet, was developed by G. Manzini (1973); another primer, on the Katía variety, was designed by Martínez and Guisao (1980). There are a catechism in the Baudó dialect (1981) and a primer by Livia Correa (1982), as well as one, by María L. Picón (1985), on the Itsmina region.

For the Waunanas, in addition to Holmer's studies, there was a phonological and grammatical study done by the Sacred Heart missionaries Sánchez and Castro (1977), with the advice of Reinaldo Binder of the SIL, and a monograph by Luz Lotero (1972).

The Embera Waunana Regional Organization (OREWA) of Choco wrote a manual for indigenous teachers (1987), within the framework of its newly initiated ethnoeducation program.

Mauricio Pardo has done phonological and grammatical descriptions of the Embera language in northwestern Antioquia and the zone of the upper Baudó River in the department of Choco. With his participation in workshops with teachers from Baudó and in 1983 in northeastern Antioquia, an era of studies began that committed both Indians and researchers to a common cause in the application of the results of linguistic studies. In 1986, Pardo proposed, together with the author of this article, a revision of the Choco dialectology established by Loewen, 1963 (see next section of this article), and has done an extensive compilation of the publication of linguistic data on this language up to 1986. This author has also concerned himself with the elaboration of language primers and sociolinguistic aspects of the ethnic group.

Present Regionalization of the Embera Indians

The first Indians denominated 'Chocos' by the Spanish were the Emberas of the upper San Juan River,

who were then known as the Simas or the Tatamás. These Indians today call themselves Chamí. This denomination would later be applied to all indigenous groups of the upper Atrato River, in the department of Choco, then known as 'Citará' or 'Citarambirá,' and to the Indians of the middle and lower San Juan, respectively called 'Poya' and 'Noanama' in the the 17th century. Based on these points, registered in colonial papers, and respecting the linguistic data obtained from present settlements, one can attempt to reconstruct the dispersion of the Chocos (see **Figures 1** and **2**).

Most of the Chamí are located along the upper San Juan River, in the Risaralda municipalities of Mistrató and Pueblorico, on the border with Choco. They have moved northward and southward along the cordillera to places like the upper Andágueda River, in southeastern Choco, to the southwestern part of the department of Antioquia in the municipalities of Jardín, Valparaíso, and Bolívar, and to the northern part of the department of the Valle del Cauca along the Garrapatas and Sanguininí rivers. Small groups are also located in other parts of Antioquia and Valle and have even moved down into the departments of Caquetá and Putumayo.

Those who were called Citarás or Citarambirás during colonial times – then located along the upper Atrato River, on the Capá River, in Lloró, and along the lower Andágueda River – have moved northward along the river to the upper Baudó River, toward the coastal tributaries to the north of Cabo Corrientes and the Panamanian portion of Darién. These river-dwelling Indians are known as 'Cholos' on the Pacific coast of Colombia.

Because these people form a distinct dialectal zone and because they are generally considered a mountain group, researchers believe the Indians who presently occupy territories in northeastern Antioquia – in Dabeiba, Frontino, Ituango, Murrí, among other places, and in the department of Córdoba, in the upper Sinú, San Jorge River, Rioverde, etc. – must descend from Emberas who, after the Conquest, settled along the eastern tributaries of the middle course of the Atrato River, a group different from the Citarás. These Indians are erroneously known as 'Katíos,' but colonial documents imply that the real Katíos succumbed toward the end of the 17th century, after a terrible struggle with the Spanish. Vargas (1990) postulated, based on archival documents, that many Katíos united both in alliance and in war with the Emberas.

The Indians encountered by the Spanish in the middle San Juan River, whom the Spanish called 'Poyá,' are believed to be the ancestors of the present dwellers of middle Baudó River, in the affluents Catrú, Dubasa, and surroundings. The Poyá presented a dialectal

Figure 1 Current Choco Dialectology. Reproduced from Pardo M (1987). 'Regionalización de indígenas choco.' In *Revista del Museo del Oro*, Boletín 18, January–April. Bogota: Musco del Oro. 46–63.

difference with the ones from the upper Baudó River. These people called themselves Emberas to differentiate themselves from the mountain people, who were called Katíos.

The Indians presently located to the south of Buenaventura also descended from the Poyás, whose main settlements are along the Saija River (department of Cauca), and the Satinga and Saquianga rivers

(department of Nariño) (Pardo, 1987). They call themselves 'Eperas,' in accordance with the phonology of their dialect.

In the department of Caldas, there are settlements of Embera Indians, known to the rest of the population as 'Memes.' They live in municipalities such as Belalcázar, Vitervo, and Riosucio, in places like La Betulia, La Tesalia, and the Indian reservations of San Lorenzo and Nuestra Señora de la Montaña. Some are Indian reservations with reserved territory, while others such as Cañamomo and Lomaprieta are in the process of becoming reservations (these are called 'partialities'). In addition to the problem of vindicating their own identity as a separate ethnic group, they have encountered major difficulties for having lost their native tongue, but nonetheless they are at present actively committed to carrying out programs to recover their language with the help of native speakers from other regions.

The Emberas who settled along the lower San Juan River and its tributaries, along the Juradó, Jampavadó, Docampadó, and Siguirisúa in southern Choco, and along the San Juan de Micay River in Cauca were called 'Nonamá' or 'Noanamá' ever since the invasion, but they call themselves 'Waunana' or 'Waunán.' Over the course of a century they have migrated to the province of Darién in Panama, where 2000 now reside, and to the Chintadó River along the lower Atrato, where there are several hundred who migrated some 20 years ago. There are estimated to be about 4000 native speakers of Waunana in Colombia. Like the Emberas, they are known as 'Cholos.' The Waunanas and the Emberas are the only two ethnic groups that can clearly be identified as presently forming part of the Choco family.

In 1988, the author of this article, together with the anthropologist/researcher Mauricio Pardo, presented a proposal for the regional classification of the Choco Indians – a revision of that proposed by J. Loewen – based on the different dialects encountered during fieldwork in the different zones with Choco Indians in Colombia. Some samples to support this proposal are presented below. These are taken from personal fieldwork notes and first appeared in an article entitled 'Dialectología Choco' in the memoirs of the seminar-workshop 'Estado actual de la clasificación de la lenguas indígenas de Colombia,' held in February 1988 at the Instituto Caro y Cuervo in Bogota (Pardo and Aguirre, 1993) (see Figure 3).

To begin, a diagram showing the present linguistic variations and the local denominations is presented (Figure 3). The proposal of Jacob Loewen is then presented (Table 1), followed by the Pardo-Aguirre proposal (Table 2). After that, the zones and specific places identified by Pardo and Aguirre are presented in detail (Table 3), along with a global diagram of said zones (Figure 4). Finally, phonological and grammatical comparisons of the Waunana language and the different dialects proposed for the Embera language (as well as among the latter) are shown (Tables 4–6).

Note: As can be seen, Loewen proposed 4 phonological systems and dialect subdivisions at the lexical level within them. Nonetheless, the recent data show that at least 6 different systems can be identified: 1 for Waunana and 5 for the different Embera dialects.

Present State of Studies on the Embera Language

Colombia, together with the other Latin-American countries, with all the richness that multiculturalism and plurilinguism represent, only in recent times has given attention to its aboriginal languages. There is not still an official position on the defense of these languages and their speakers, who are not extinct, thanks to their proper fight and the support of a sector of the civil population. Just during the last 20 years of the 20th century were the Indian and Afro-Colombian languages, still alive in the national panorama, taken seriously by academia.

In 1984, the Anthropology Department of Andes University instituted a Masters in ethnolinguistics, with the sponsorship of the Centre Nationale de la Recherche Scientifique (CNRS) of France. In the program, researchers are prepared for the study of

the native and Afro-Colombian languages, their eventual goals being publication, conservation, and strengthening of these languages. The program's students and professors constitute the Centro Colombiano de Estudios de Lenguas Aborígenes (CCELA), through which they do the scientific work of the rescue and fortification of these languages. With these linguist students, a new era in the research and promotion of the aboriginal and creole languages of the country has begun, with them covering the entire national territory, doing fieldwork and linguistic data analysis *in situ*. This has yielded an awakening of these communities for the rest of Colombian population and even for themselves.

Several students from the program have done research on the Embera language:

Rito Llerena Villalobos. He was a student from the first promotion, having finished the program in 1987. He is now a professor at Universidad de Antioquia, in the Department of Linguistics. From 1989 to 1992, he worked on compared phonology of the Amerindian languages of Antioquia, including the Tule language (of the Cuna Indians), subject of his degree thesis (1987). This researcher has worked lately on the Embera language, creating didactic materials for the Indian teachers of Alto Andágueda, phonological and morphological research in the Embera Reservation of

Figure 4 Choco dialectology.

Jaidukamá, department of Antioquia, and collaborating in ethnoeducation among the Emberas of Tierralta, upper Sinú River, in the department of Córdoba, where he is working at present. In the year 2000 he wrote a report on the grammar and phonology of the Tule language for the Instituto Caro y Cuervo.

Mario Hoyos Benites. He, too, was a student from the program's first promotion and finished in 1987. At present he is a professor at the Universidad de la Guajira. He worked in 1984 in the Napipí and middle Atrato rivers and other places in the region. His research has addressed everything from the design of didactic material for Indian teachers around all the country (1991) to interdialectal phonology. He presented a report on the Embera language for the Atlas Etnolingüístico de Colombia of the Instituto Caro y Cuervo in 1997, and wrote a report (2000) on the Embera language of the Napipí River for the institute.

Notes: Details regarding the zones and specific places of the Choco proposed by Pardo and Aguirre. **Waunana:** lower San Juan River, Docampadó, coastal rivers, Juradó, Panama, Chintadó. **South Coast:** Saija, Satinga, Saquianga, Naya, Cajambre, south of Buenaventura. **Lower Baudo:** Catrú, Dubasa, coastal rivers, Purricha, Pavaja. **Upper San Juan:** Chamí, Tadó, upper Andágueda River, southwest of Antioquia Department, Garrapatas River (north of Valle Department). **Antioquia/Córdoba:** Dabeiba, Murrí, Riosucio, upper Sinú and San Jorge Rivers. **Atrato:** upper Atrato River, Capá, Bojayá, upper Baudó River, Panamá. Actually, the difference among the diverse phonological inventories is in the plosive systems and the voicing of the sibilant /s/ and the palatal affricate. Hence, the global scheme outlined in **Table 3** can be suggested.

Table 5 Grammatical similarities and differences

	Waunana	*South Coast*	*Upper San Juan*	*Antioquia Córdoba*	*Atrato Panamá*
Ergative/Instrumental/Attributive	a/au/iu	a/pa	a/ba	a/ba ± ra	a/ba
Intransitive/Accusative	ø/ta	ø/ta	ø/ra	ø/ra/a	ø/ra/da
Previous Reference	ø	ø	ra	ra	ra
Dative	ik	ma/ǰa/a	a	a	a
Benefactive	it^{h}ee	it^{h}e	ita	ita	ita
Sociative	dʉi	ome	ome	umé	ume
Situative	e	de	ďe	ðe	ďe
Alative	g	ma	m/ďa	eða	ďa
Ablative	mu	depa	ďeba	ðeba	ďeba

Table 6 Basic sentence order

	S	*O*	*V*
1. Waunana	saak-iu	berúč	k^{h}aahím
	perro- erg	tatabro	mordió
2. South Coast	usa-pa	et^{h}érre	peehí
	perro-erg	gallina	mató
4. Upper San Juan	ũẽrã-ba	mũ-buda	kõsí
	mujer-erg	mi pelo	cortó
5. Antioquia/Córdoba	ũẽrã-ba	ũãũã-ra	ubeasía
	mujer-erg	niño-ac	pegó
6. Atrato/Panamá	hãĩbana-ba	kauzake-da	ʉratʉsía
	chamán-erg	niñita-ac	frotó

Common characteristics: 1. Predominant suffixing. 2. Occasional prefixing: integration in nominals, some verbal aspectualizing. 3. Varients of: number, gender, affection, position, permanence in the auxiliary. 4. Tactical order variation for focalization. 5. Verbalized lexical determination (adjectival verbs). 6. Actancy, opposition: agent, attributive, instrumental versus intransitive subject, accusative. 7. Great variation in prenominal suffixing. 8. Basic S O V order.

Ernesto Llerena García. He completed the program in 2001, with a dissertation titled 'La predicación de la oración simple en la lengua embera del Alto Sinú' (simple sentence predication of the Embera of Atto Sinú). He has been profesor of linguistics at the Antioquia and Córdoba universities, where is working at the moment. With his father, Rito Llerena, and the Emberas of upper Sinú River, he wrote *Diccionario etnolingüístico de la lengua Embera* (2003) for the Normal Superior de Montería (capital of the department of Córdoba).

Daniel Aguirre Licht. A student from the second promotion, he finished up in 1989. In 1985, he began phonological studies of Chamí, southeast of the department of Antioquia. He continued with morphological studies in 1987, and then morphophonological and grammarians in 1998. In 1988, he collaborated with the anthropologist Mauricio Pardo in research on Choco dialectology; included in the resulting article (Pardo and Aguirre, 1993) was an answer to Paul Rivet's hypothesis about the origin Karib of the Choco languages. Aguirre Licht also worked in the department of Risaralda, the location of the Indian reservation Embera-Chamí of Purembará (from *puru* = 'town' and *embera*), a possible place of the dispersion of the different Embera groups at the Spanish arrival, and he has also worked with the Emberas of Garrapatas Valley, in the department of Valle del Cauca.

About the Waunana there are also the works of Gustavo Mejía (1987), another student from the first promotion of the master's in ethnolinguistics of the Universidad de los Andes. He did a grammarian investigation in 1987 as his thesis. He also did, for the Instituto Caro y Cuervo, a phonological and morphosyntactic description of Waunana (2000b) and a presentation of the aboriginal languages of the Pacific coast of Colombia (2000a).

Edel Rasmussen, who worked at the Universidad Nacional de Panamá, studied the Embera language of the Panama area and published research on phonology (1986) and on grammar (1985).

The Technological University of Pereira (UTP), located in the capital of the department of Risaralda, has paid attention the great number of the Embera-Chamí Indians who live in the department, both in studies of their language and in projects on other matters. Fernando Romero L. of the Psycho-Pedagogy Department in the School of Education does research on linguistic and pedagogical problems of the teaching of Spanish as a second language with bilingual Chamí and Nasa (Páez) teachers, as well as on discourse analysis of this variety of the Embera language, including studies in which the author of this article has participated. Linguist Olga L. Bedoya works with him, and as Director of the Ethnoeducation and Community Development Program in the same school she does research on the interference of Spanish in different Embera dialects, problems of orality versus writing, and other aspects of Embera language and culture.

Chomsky, Noam (b. 1928)

J B Walmsley, Universität Bielefeld, Bielefeld, Germany

© 2006 Elsevier Ltd. All rights reserved.

Noam Avram Chomsky (Figure 1) was born in 1928 in Philadelphia, Pennsylvania, and studied at the University of Pennsylvania. From 1951 to 1955 he was a junior fellow of the Harvard University Society of Fellows, completing his Ph.D. in linguistics in 1955. In that year he took up a post in the Department of Modern Languages and Linguistics at Massachusetts Institute of Technology. From 1958 to 1959 he worked at the Institute for Advanced Study at Princeton. From 1966 to 1975 he held the Ferrari P. Ward Professorship of Modern Languages and Linguistics, and was appointed Institute Professor in 1976.

Chomsky's thinking has had a radical influence on grammar theory and the philosophy of grammar, syntax, morphology, language acquisition, phonology, and the historiography of linguistics. His linguistic work (the other half of his life is devoted to political writing) can be divided into four main phases: an early phase (the 1950s); a classical phase (1960s and 1970s); a transitional phase, in the 1980s; and a new phase in the 1990s, in which the 'minimalist program' was introduced.

The first work of Chomsky's to make a wider impact was *Syntactic structures* (1957), which introduced a new way of looking at grammar and language that opened up exciting avenues of enquiry. In this book Chomsky circumvented the debate as to what constituted a sentence by postulating it as a primitive in his system. According to *Syntactic structures*, a language was "a set ... of sentences, each finite in length and constructed out of a finite set of elements" (Chomsky, 1957: 13), and "the fundamental aim in the linguistic analysis of a language L is to separate the grammatical sequences which are the sentences of L from the ungrammatical sequences which are not sentences of L ... The grammar of L will thus be a device that generates all the grammatical sequences of L and none of the ungrammatical ones." 'Grammatical' did not mean 'meaningful,' as the sentence 'Colorless green ideas sleep furiously' showed, which, while not being uncontroversially meaningful, is syntactically well-formed. In *Syntactic structures* Chomsky also introduced the concept 'generative' to mean not only productive, but also formally explicit. Chomsky argued that neither finite-state nor phrase-structure (PS) grammars were adequate as a means of generating the sentences of a natural language, and introduced a transformational component by means of which further operations could be performed on the output of a PS-component to generate the strings that underlie sentences. Finally, this study emphasized the evaluative function of grammar theory (in selecting the best grammar) as opposed to the discovery procedures favored by the preceding generation.

Figure 1 Noam Chomsky.

Aspects of the theory of syntax (Chomsky, 1965) marked an increasing interest in grammar as reflecting the structure of the human mind. This work introduced the notions of *competence* (a speaker's ability to produce and understand correct sentences) and *performance* (the externally verifiable product of such competence), and also deep- and surface-structure. This study is the source of his classic statement, "Linguistic theory is concerned primarily with an ideal speaker-listener, in a completely homogenous speech-community, who knows its language perfectly and is unaffected by such grammatically irrelevant conditions as memory limitations, distractions, shifts of attention and interest, and errors ... in applying his knowledge of the language in actual performance" (Chomsky, 1965: 3). This approach to grammar became known as 'standard theory' (ST). Keen to distance himself from his immediate predecessors, Chomsky stressed the affinities between transformational grammar and so-called traditional grammar: "It would not be inaccurate to regard the transformational model as a formalization of features implicit in traditional grammars, and to regard these grammars as inexplicit transformational generative grammars" (Chomsky, 1964: 918).

Standard theory raised questions about the nature of a deep structure that postulated identical representations for synonymous sentences, about the nature of global and cross-derivational constraints, and about how illocutionary force could or should be incorporated into the syntax. Differences on these issues led to a split in the movement, with 'generative semantics' being rejected by Chomsky and some of his associates in favor of an 'interpretive semantics' (Huck and Goldsmith, 1995).

After *Aspects* Chomsky published successive revisions in what came to be known as 'the generative enterprise,' each of which is characterized by a key work. 'Standard theory' was followed by 'extended standard theory' (Chomsky, 1973) and 'revised extended standard theory' (Bach, 1977), which introduced the concept of 'core grammar' and periphery, and devoted much attention to conditions and filters. It then became 'government-(and)-binding theory' (Chomsky, 1980, 1981), which introduced θ-roles ('semantic' or 'thematic relations'), and replaced deep- and surface-structure by 'D-structure' and 'S-structure,' though not with identical meanings.

Up to this point the goal of Chomskyan theory had been the writing of grammars of natural languages. The next – transitional – phase saw a move toward a different goal – exploring the principles of universal grammar. This – Chomsky's 'second conceptual shift' (Chomsky, 1986: 6, 145) – was pursued within the theory of 'principles and parameters.' Competence and performance were replaced by the (partly overlapping) 'I-language' (internalized language as a property of the human mind) and 'E-(externalized)-language' (speech written or oral). Principles and parameters are properties of all human languages (part of innate UG), but the principles are invariable whereas the parameters can have different settings. Thus the 'projection principle' ("lexical structure must be represented categorially at every syntactic level" – Chomsky, 1986: 84) is assumed to apply to all human languages. But the 'head parameter' will specify by its setting for a given language whether the head typically comes first in a construction (followed by its complements, as in *bought the book*) or last (as in Japanese).

Principles and parameters theory was succeeded in the 1990s by the 'minimalist program' (Chomsky, 1995). The change in terminology from 'theory' to 'program' is significant. The question had now become, 'How perfect is human language?' The minimalist program is driven by the view that human language is maximally simple, and by a striving for economy – economy of representation, economy of principles, and economy of derivation.

Although *Syntactic structures* contained little evidence of the degree to which grammar theory and language acquisition theory were to merge, there was evidence as early as the 1950s of the challenge that Chomsky's ideas were to pose in psycholinguistics. In his review of Skinner's *Verbal behavior* (Chomsky, 1959), Chomsky both attacked behaviorist theories of language acquisition and opened up new avenues for research: "The fact that all normal children acquire essentially comparable grammars with remarkable rapidity suggests that human beings are somehow specially designed to do this, with data-handling or 'hypothesis-formulating' ability of unknown character and complexity" (Chomsky, 1959: 57). The question was how, on the basis of the available data, the child manages to construct a grammar of its mother tongue: "A consideration of the character of the grammar that is acquired, the degenerate quality and narrowly limited extent of the available data, the striking uniformity of the resulting grammars, and their independence of intelligence, motivation, and emotional state, over wide ranges of variation, leave little hope that much of the structure of the language can be learned by an organism originally uninformed as to its general character" (Chomsky, 1965: 58).

The information that 'the organism' possessed to deal with this task was characterized as a 'language acquisition device,' a 'black box' that, while one had no direct access to its contents, nevertheless permitted hypotheses to be made about its workings on the basis of its output. A search for universals of language acquisition was thus under way that ultimately turned into the task of describing the properties of I-language.

In the mid-1960s Chomsky concentrated on grammar theory, phonology, and the history of ideas. The position adopted in *The sound pattern of English* (Chomsky and Halle, 1968) illustrates a general move away from structuralist taxonomic description toward the generative paradigm. *The sound pattern of English* made use of a set of primitive terms together with a set of rules for combining them and for linking the morphophonemic, phonological, and phonetic levels by means of transformations. The system was symbol-based and formally defined, with rules of the form $A \rightarrow B/X____Y$ (to be read as: 'interpret – or re-write – A as B when it appears in a context preceded by X and followed by Y'). In the early stages, interest focused on the nature of phonological rules, rule ordering, and the cyclic nature of rules. Though – or perhaps because – *The sound pattern of English* presented a theory that was essentially one-dimensional, not fully fleshed out, and language specific, it too stimulated further research.

In that volume and elsewhere Chomsky preferred to look back to the work of earlier grammarians as opposed to his structuralist predecessors. In 1966 he published *Cartesian linguistics,* in which he argued that his innateness theory was not simply the product of a backlash against behaviorist views, but had a much longer pedigree. This work was sharply reviewed, notably by Salmon, who showed that even in Descartes' time proponents of innateness theories were locked in combat with empirical-sensualist theorists. Despite Chomsky's disclaimers in the book, the consensus view seemed to be that *Cartesian linguistics* was not a model of how to write the history of linguistics. It says something for Chomsky's stature, though, that his excursion into the history of linguistics acted as a powerful stimulus to younger scholars (Walmsley, 2000).

Chomsky's work dominated the second half of 20th-century linguistics like that of no other linguist. The switch from a taxonomic, inductive, descriptive approach to a generative, hypothetico-deductive, 'explanatory' approach left an indelible mark on how we do syntax, morphology, and phonology today. It increased precision by committing itself to symbolic representation and formalization. The increase in precision, though, came at a price: the scope of 'linguistics' narrowed. Since a language was said to be "a set of structural descriptions of sentences, where a full structural description determines (in particular) the sound and meaning of a linguistic expression" (Chomsky, 1977: 81), the focus of attention moved in effect from 'language' to 'grammar.'

Chomsky, of course, was not the only source of linguistic ideas in the 20th century, but it would be difficult to grasp much of modern linguistics without some understanding of his ideas and techniques. His ideas have proved fruitful not only in themselves, but also in the reactions they provoked within morphology, syntax, and elsewhere. Underlying almost all these theories however are frequently untested assumptions about the fundamental categories of language – word classes, attributes, and their values. The energy invested in the Chomskyan paradigm has in part deflected attention from these issues. As Lyons put it: "in *Aspects* . . ., as generally, Chomsky was . . . content to operate, uncritically, with the categories and subcategories of traditional grammar" (Lyons, 1989: 167). These categories have hardly been questioned by the big commercial grammars, either.

Chomsky's influence has left its mark on mathematical linguistics, historical linguistics, theories of language acquisition, anthropology, the study of human cognition, biology, philosophy and the philosophy of science, artificial intelligence, logic, music theory, literary theory, law and theology, among other fields (Otero, 1994).

Chorasmian

P O Skjærvø, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

Chorasmian was an Iranian language spoken in medieval Chorasmia, a state on the Oxus/Amu Darja south of the Aral Sea. The name is first mentioned in the Avesta and the Achaemenid inscriptions (*see* **Avestan; Persian, Old**) but the language is known only from much later times. Several words pertaining to the calendar and astronomy were cited by Abu Rayhan Biruni in his *Athar al-baqiya* (comp. 1000). Since then archeological excavations have uncovered inscriptions and documents on parchment and wood from ca. 200–700 A.D.; also, a number of manuscripts of Arabic works containing interlinear glosses in Chorasmian have been found in libraries in Turkey, notably Abu'l-Qasim Zamakhshari's *Muqaddimat al-adab* (ms. from ca. 1200) and several 13th-century Arabic law books. The Chorasmian glosses are written in Arabic script, with several modified letters. Those in the *Muqaddima* are often underpointed or not pointed at all, which makes them hard to interpret.

Some Arabo-Persian letters were modified to express special Chorasmian sounds. Triple superscript dots over *c* = *ts* and *dz*, over *f* = *β*. Triple subscript dots were used under *s* to indicate *s*, not *š*, and single subscript dot under *d* to indicate *d*, not *δ*.

Chorasmian historical phonology is characterized by extensive affrication of dentals, palatalization, and a variety of, often unpredictable, simplifications of consonant groups. For instance, *t* and *d* > *c* [ts] and *j* [dz] before and after *i*, *y*: *pc* < *pati-* (preverb) and **pitā* 'father'; *pzy* 'sinew', cf. Av. *paiδiiā-*. Intevocalic *š* developed variously: *'mh* 'ewe', cf. Av. *maēšī-*; *mwf* 'mouse', cf. Av. *mūš*; *γwx* 'ear', cf. MPers. *gōš*; etc.

The Chorasmian vowel system is characterized by the reappearance (in the script) of final vowels before suffixes, *pc* = *pic*^{a} 'father', but *pc'm* = *picā-m*^{i} 'my father'. Contraction of final vowels with vowels of suffixes is common, e.g., *hāβ*^{i}*r-īn*^{a} 'give.IMPERF-1ST.SING' = 'I gave', but *hāβir-*^{i}*n*^{a}*-h*^{i}*-d*^{i} 'give.IMPERF-1ST.SING-he/she/it.ENCL.OBL-you.ENCL.OBL' = 'I gave her to you' > *hāβir-nā-hī-d*^{i} > *hāβir-n-ī-d*^{i}. Such final vowels are sometimes indicated by the Arabic vowel marks.

Masculine and feminine gender are distinguished in the definite article (*ĭ*, *ya*; *-ĭ*, *-ă* after prepositions) and in declension (nom. sing. masc. no ending, but fem. *-a*). Five cases are distinguished in masculine nouns: nominative-accusative, vocative (*-a*), possessive (*-ān*), dative (*-i*), and ablative-locative (*-a*), but feminine nouns have only two forms: nominative and locative (*-a*) contrasting with the other cases (*-iya*). The plural endings are *-i* or *-ina*, possessive *-in-ān*. A final *-k* becomes *-c* before *-i*. The direct object can be marked by *-δār* attached to the dative (presumably < **rāδ*, cf. Pers. *-rā*). Examples: *ī kām-h*^{i} 'DEF mouth.MASC-he.ENCL.OBL 'his mouth'; *f-ī kāmā-h*^{i} 'in DEF mouth'; *yā camā-h*^{i} 'DEF eye.FEM-he.ENCL.OBL'; *yā cam-yā-h*^{i} *δār* 'DEF eye.FEM-DAT-he.ENCL.OBL' = 'his eye' (DO); *ī βandik* 'the servant', *ī bandic-*^{i} 'the servants', *f-ī bandic-ī-h*^{i} 'with-DEF servant-PL-he.ENCL.OBL' = 'with his servants'; *ī bfin-ēnik ī βūm-in-ān* 'DEF create.AGT DEF earth-PL-POSS' = 'the creator of the earths'.

When several enclitic personal and local pronouns are added to a verb, the order is strict, e.g., *γēr-īdā-hī-nā-bir* 'turn-IMPERF.3RD.SING-he.ENCL.OBL-they.ENCL.OBL-upon' = 'he made them go around him', where *-bir* goes not with the preceding *-nā-*, but with *-hī-*. When personal and local complements follow the verb, they must be anticipated as enclitics, e.g., *m-uxwās-idā-nā-w*^{a} *f-ī razik-*^{a} *ī cūb* 'IMPERF-let-PAST.3RD.SING-they.ENCL.OBL-there in-DEF-vinyeard-LOC DEF-water.PL' = 'he let the water into the vinyeard'; *hīδ-idā-hī-nā-dā-bir ī salām* 'read.IMPERF.3RD.SING-it.ENCL.OBL-they.ENCL.OBL-there-on DEF-greeting.PL' = 'he recited the greetings upon him'.

The verbal system is of the Eastern Middle Iranian type. There are three stems: present, past, and perfect (perfect participle = past stem + suffix *-ik*, FEM *-ic*^{a}). There are numerous modal forms (indicative, imperative, subjunctive, optative, injunctive); an imperfect formed with prefixes (*m-ikk-* 'did') or lengthening of the vowel of the first syllable (*h-ā-βir-* 'gave'), both reflexes of the Old Iranian augment; a form ending in *-ī(n)* added to personal endings, the function of which is not completely clear but which is referred to as 'permansive'; a (present) perfect formed with the perfect participle and the verb *δār-* (transitive verbs) or 'be' (intransitive verbs), e.g., *akt-ik δāriy-ā-yī* 'do.PERF.PART.MASC have.PRES-1ST.SING-PERMANSIVE' = 'I may have done'; *purāc*^{a}*-ihi* [<*purād-c-*]> *purācīhi* 'divorce.PERF.PART.FEM-be.PRES.2ND.SING' = 'you are divorced'.

Christianity and Language in the Middle Ages

N Adkin, University of Nebraska, Lincoln, NE, USA

© 2006 Elsevier Ltd. All rights reserved.

Christianity was founded by a carpenter's son and spread by fishermen. Since the first Latin versions of the Bible were produced for very humble folk, their language was correspondingly humble; it was also marked by lexical and syntactic Hebraisms and Hellenisms. For educated pagans of late antiquity, the problem with Christianity was not theological, but linguistic: the language of its scriptures was simply considered too crude. While, moreover, the case made by the 'Nijmegen School' for a specifically Christian sociolect would seem to be untenable, the works of Christian writers were sufficiently unclassical to make educated pagans turn up their noses. When the highly educated Cyprian embraced Christianity, a pagan dubbed him instead *Coprian* ('Mr. Shit').

The educational system that produced such people consisted of two parts. Broadly speaking, the role of the 'grammaticus' was to teach correct Latin and to expound the classics. The 'rhetor' then coached the student in the five parts of rhetoric: invention, disposition, style, memory, and delivery. Style (*elocutio*) comprised figures of language (e.g., *adiunctio*, *anaphora*, *anastrophe*, *annominatio*, *asyndeton*) and figures of thought (e.g., *aetiologia*, *allegoria*, *aposiopesis*, *apostrophe*, *aversio*). The problems posed by such an educational system for Christians are conveniently illustrated by the two greatest of the doctors of the Church: Jerome and Augustine. Jerome had been the star student of Donatus, the doyen of grammatici. When as a hermit Jerome preferred the stylistic finesse of Cicero to the rebarbative language of the Old Latin Bible, he had a famous dream, in which he was hauled before God's throne and told: 'You are a Ciceronian, not a Christian'. Augustine had been a professional rhetor himself. When as a bishop he then wrote the *De doctrina christiana*, the only use he could find for the old educational system was as an ancillary to the better understanding of the Bible.

Both Jerome and Augustine lived to see the fall of Rome. The barbarization and ruralization resulting from the influx of hordes of illiterate Germans led ultimately to the collapse of the old educational system. With the end of Roman rule, private and public libraries began to disappear. The books that survived usually found refuge in the monasteries, which had developed in the fifth century, when the appeal of a life of ascetic withdrawal grew. Such monasteries were also in a position to provide education. A similar function could be performed by the schools that came to be attached to cathedrals. Education accordingly became the preserve of the Church: a clerk is now a 'cleric'.

If Christians like Jerome and Augustine had been ambivalent in their attitude toward classical education, 6th-century monks like Benedict and Gregory the Great rejected it decisively. Benedict's Rule makes his monks copy books, but Benedict himself had run away from school and composed his Rule in Vulgar Latin; the books he had in mind were naturally Christian. The prefatory letter to Gregory's *Moralia in Iob* proclaims its author's resolute refusal to trammel the Word of God with the "rules of Donatus." His friend Gregory of Tours wrote a particularly solecistic Latin that showed how far the language had advanced toward Proto-Romance and how close to each other its written and spoken forms had become.

Throughout the Dark Ages the light of learning still shone in Ireland, which had received Christianity in the 5th century. At the same time the Irish also received Latin, which as the language of the Bible, the Liturgy, and the Church Fathers was the indispensable concomitant of the new religion. The Irish also did not share the unease of their continental coreligionists with the pagan classics, since Ireland had never known Roman paganism. In addition, because in Ireland Latin was the preserve of an educated elite, the language was not exposed to the evolutionary tendencies that affected it on the increasingly Romance-speaking continent. Irish monks were therefore able to bring Christianity and a fairly classical form of Latin to their neighbors, the English.

Christianity and Language in the Middle Ages

N Adkin, University of Nebraska, Lincoln, NE, USA

Christianity was founded by a carpenter's son and spread by fishermen. Since the first Latin versions of the Bible were produced for very humble folk, their language was correspondingly humble; it was also marked by lexical and syntactic Hebraisms and Hellenisms. For educated pagans of late antiquity, the problem with Christianity was not theological, but linguistic: the language of its scriptures was simply considered too crude. While, moreover, the case made by the 'Nijmegen School' for a specifically Christian sociolect would seem to be untenable, the works of Christian writers were sufficiently unclassical to make educated pagans turn up their noses. When the highly educated Cyprian embraced Christianity, a pagan dubbed him instead *Coprian* ('Mr. Shit').

The educational system that produced such people consisted of two parts. Broadly speaking, the role of the 'grammaticus' was to teach correct Latin and to expound the classics. The 'rhetor' then coached the student in the five parts of rhetoric: invention, disposition, style, memory, and delivery. Style (*elocutio*) comprised figures of language (e.g., *adiunctio*, *anaphora*, *anastrophe*, *annominatio*, *asyndeton*) and figures of thought (e.g., *aetiologia*, *allegoria*, *aposiopesis*, *apostrophe*, *aversio*). The problems posed by such an educational system for Christians are conveniently illustrated by the two greatest of the doctors of the Church: Jerome and Augustine. Jerome had been the star student of Donatus, the doyen of grammatici. When as a hermit Jerome preferred the stylistic finesse of Cicero to the rebarbative language of the Old Latin Bible, he had a famous dream, in which he was hauled before God's throne and told: 'You are a Ciceronian, not a Christian'. Augustine had been a professional rhetor himself. When as a bishop he then wrote the *De doctrina christiana*, the only use he could find for the old educational system was as an ancillary to the better understanding of the Bible.

Both Jerome and Augustine lived to see the fall of Rome. The barbarization and ruralization resulting from the influx of hordes of illiterate Germans led ultimately to the collapse of the old educational system. With the end of Roman rule, private and public libraries began to disappear. The books that survived usually found refuge in the monasteries, which had developed in the fifth century, when the appeal of a life of ascetic withdrawal grew. Such monasteries were also in a position to provide education. A similar function could be performed by the schools that came to be attached to cathedrals. Education accordingly became the preserve of the Church: a clerk is now a 'cleric'.

If Christians like Jerome and Augustine had been ambivalent in their attitude toward classical education, 6th-century monks like Benedict and Gregory the Great rejected it decisively. Benedict's Rule makes his monks copy books, but Benedict himself had run away from school and composed his Rule in Vulgar Latin; the books he had in mind were naturally Christian. The prefatory letter to Gregory's *Moralia in Iob* proclaims its author's resolute refusal to trammel the Word of God with the "rules of Donatus." His friend Gregory of Tours wrote a particularly solecistic Latin that showed how far the language had advanced toward Proto-Romance and how close to each other its written and spoken forms had become.

Throughout the Dark Ages the light of learning still shone in Ireland, which had received Christianity in the 5th century. At the same time the Irish also received Latin, which as the language of the Bible, the Liturgy, and the Church Fathers was the indispensable concomitant of the new religion. The Irish also did not share the unease of their continental coreligionists with the pagan classics, since Ireland had never known Roman paganism. In addition, because in Ireland Latin was the preserve of an educated elite, the language was not exposed to the evolutionary tendencies that affected it on the increasingly Romance-speaking continent. Irish monks were therefore able to bring Christianity and a fairly classical form of Latin to their neighbors, the English.

Accordingly, Alcuin was in turn summoned by Charlemagne from the cathedral school in York to his capital Aachen, where this well-educated Englishman masterminded the Carolingian renaissance.

This renaissance entailed a revival of classical education. As a species of Carolingian 'minister of culture', Alcuin established the trivium of 'grammar', 'rhetoric', and 'dialectic'. He thereby bequeathed to the Middle Ages a tradition of writing correct and cultivated Latin, which were the objectives of grammar and rhetoric, respectively, while dialectic taught correct thinking. Texts of the pagan authors became once again the subject of diligent study instead of being ignored or destroyed; their dissemination was also facilitated by the new Carolingian minuscule (writing style). Donatus was reinstated as the arbiter of acceptable usage. Zealous attention was now paid to his two *Artes*, both of which set out the eight parts of speech. While the longer treatment dealt with the *vitia et virtutes orationis*, the shorter one, with its congenial question-and-answer layout, became the favorite grammar for beginners throughout the rest of the Middle Ages. Henceforth, Latin was treated as a learned language separate from Romance.

However, some qualifications must be noted to this rosy picture of linguistic and literary renaissance. The unclassical features that had marked the style of the Church Fathers persisted; here particular mention may be made of the use of *quod*, *quia,* and *quoniam* rather than the accusative and infinitive, of the use of the infinitive to express purpose, of a tendency to employ prepositions indiscriminately, and of a greater license in the handling of tense and mood. Similar divergencies from the classical language characterized Jerome's massively influential Vulgate version of the Bible, which by the Carolingian period had generally replaced the stylistically hair-raising Old Latin translations that had so repelled him in his youth. The Bible and writings of the Church Fathers alone seemed an appropriate object of study to some religious leaders, who disapproved of the use of pagan texts; Alcuin himself had felt qualms, although Christian allegories were always an option. Even when such reservations were absent, the goal was always a proper understanding of Holy Writ. Charlemagne's own motivation had been largely pragmatic, since he wished to improve the quality of officials for Church and State. Moreover, there is evidence that in the decades following Charlemagne's death, his educational reforms were not being systematically implemented.

Such as it was, this Carolingian renaissance was effected through the schools that were attached either to monasteries (e.g., Fulda, St. Gall, Tours) or to cathedrals (e.g., Metz, Orléans, Reims); such establishments were the forerunners of the great monastic and cathedral schools of the High Middle Ages. Charlemagne's own biographer Einhard was himself an alumnus of Fulda; his masterpiece, the *Vita Caroli*, illustrates the new enthusiasm for the classics by its studious imitation of Suetonius's *Vita Augusti*. If in matters of grammar the Carolingian age preferred to rely on the handily succinct Donatus, he was eclipsed in the 11th century by Priscian's much ampler *Institutiones grammaticae*, which likewise deals with the eight parts of speech. For rhetorical instruction the main textbooks continued to be the pseudo-Ciceronian *Rhetorica ad Herennium* and Cicero's juvenile *De inventione*; the latter had inspired Alcuin's own *De rhetorica et de virtutibus*.

Medieval authors produced numerous commentaries on these four key manuals of grammar and rhetoric as well as textbooks of their own that derive from them; here, passages from Christian works could be used for exemplification in place of pagan ones. Of the rhetorical handbooks, the *Rhetorica ad Herennium* in particular sets out its subject with admirable clarity and comprehensiveness. Its fourth book, which often circulated separately, is devoted to a very full treatment of the 64 figures of language and thought. Lavish use of these figures in Walter of Châtillon's 12th-century *Alexandreis* enabled this epic to outrank even Virgil's supposedly incomparable *Aeneid* in the favor of the schools.

This same 12th century saw a weakening of the Church's role in the teaching of Latin. Here a number of factors were involved. First, the new orders of Cistercians and Carthusians admitted only adults, so they did not maintain schools. Second, this period was marked by the emergence of so-called private schools, some of which developed in the following century into the universities. Last, a large number of 'grammar schools' appeared. While the old monastic schools continued to exist, their importance accordingly declined in the face of this competition from urban centers. The final point to be made in this connection is that the role of these monastic schools in education had for the first time made education available at a higher level to women, who learned Latin as nuns.

If the 12th century had managed to equal the *auctores*, in the 13th the study of them succumbed to dialectic. Rhetoric itself now tended to be reduced to the 'ars dictaminis', which was principally concerned with imparting a good prose style for the composition of letters. Here the Ciceronian arrangement of a speech into 'exordium', 'divisio', 'narratio', 'confirmatio', 'refutatio', and 'peroratio' was condensed to 'salutatio', 'narratio', 'petitio', and 'conclusio'. Careful attention was also given to 'cursus', whereby three

principal types of accentual cadence were employed at the ends of sentences: 'planus' (´- -´-), 'tardus' (´- -´- -´-) and 'velox' (´- - -´-). In connection with such 'artes dictaminis,' reference may also be made to the 'artes poetriae' and to the specifically Christian 'artes praedicandi'. These two kinds of manual-issued precepts for the writing of poetry and sermons, respectively: while the 'ars praedicandi' dealt chiefly with the division and amplification of a theme, the 'ars poetriae' laid particular stress on the figures of language and thought expounded in the fourth book of the *Rhetorica ad Herennium*.

In the sphere of grammar this period saw the rise of the Modistae, whose 'grammatica speculativa' set about applying to Priscian the new methods of scholastic logic; it now went beyond his morphology to embrace syntactic analysis. Grammar accordingly came to be perceived as possessing a universal character that transcended individual languages: the grammatical 'modi significandi' reflected the mind's 'modi intellegendi', which in turn reflected the 'modi essendi' of reality itself. While moreover Priscian's examples had been taken from the *soigné* language of the classics, the scholastically minded Modistae devised their own, which in comparison were often bizarrely utilitarian.

A word should also be said about the effect of scholasticism on the Latin language itself. While Medieval Latin as a whole had always been prone to admit neologisms, this tendency was particularly characteristic of scholastic Latin. Here, particular importance was attached to the use of suffixes (e.g., *certitudinaliter*) and to the substantivization of adjectives (e.g., *haecceitas*), participles (e.g., *ens rationis*) and infinitives (e.g., *pro posse*). The result was a Latin that was precise but unclassically inelegant. Classical elegance returned with the Renaissance humanists, whose obsession with it killed Latin as a general means of communication; even the grammars of Donatus and Priscian were rejected in favor of observing the usage of classical authors themselves. Such aspirations to linguistic classicism could moreover entail an intermittent neo-paganism that tended to disown Christianity itself.

A brief mention must also be made of languages other than Latin. Educated Romans of the classical period had been bilingual, since they were equally proficient in Latin and Greek. By late antiquity, however, knowledge of Greek in the West was on the wane. During the Middle Ages, Greek was largely unknown, even though it was the language of both the New Testament and of Aristotle, who exercised a vast influence on scholasticism. Likewise, Hebrew, the language of the Hebrew Bible, was hardly known. In both cases the Middle Ages relied instead on Latin translations. The vernaculars also were largely unimportant until the late Middle Ages, since they lacked the prestige of Latin, which was felt to be the language of theology, the most important of the sciences.

The involvement of the Christian churches in issues of language has been central both to the modern linguistic history of sub-Saharan Africa and to the life of the churches themselves. Apart from Swahili in the east and Fulfulde and two or three others in the more Islamized west, none of the languages of sub-Saharan Africa had been given a written form prior to the coming of missionaries.

Early Missionary Translation Work

The earliest extant Bantu text is a lengthy catechism in Portuguese and Kongo produced by the Jesuit Mattheus Cardoso and printed in Lisbon in 1624. This, a subsequent Kongo dictionary by a Capuchin, Georges de Geel, and a grammar produced by another Capuchin, Giacinto Brugiotti da Vetralla in 1659, are immensely valuable for Bantu linguistic history. The last includes the Bantu noun-class and concord system. Unfortunately, the Catholic missionaries of that era produced little work in any other language. It was the 19th-century Protestant missionaries, with their far higher conviction of the necessity of Bible translation, who produced a mass of linguistic work – dictionaries, grammars, and biblical texts for scores of languages in every part of Africa. The pioneering work of Krapf in the east, van der Kemp, Moffat, Appleyard, and Colenso in the south, and Raban, Schön, and Crowther in the west – to name but a few from the early and middle years of the 19th century – stands for a vastly larger undertaking that has as yet received no adequate historical survey. In almost every African language with a written literature, missionaries have been responsible for the basic work and indeed for most subsequent published literature as well, except in a handful of the larger languages. The vast multiplicity of African languages and the policy of most colonial and postcolonial governments to use English, French, or Portuguese for educational purposes mean that (apart from some score of languages, such as Yoruba, Swahili, Shona, and Ganda) there is still little, if anything, of any extent published in most languages except for church purposes.

Missionary Imposition of a Dialect as a Language

Missionaries could not, of course, have done this work without African collaborators who had themselves first learned English. Inevitably the precise language canonized by missionaries, in the first dictionaries and New Testaments, was the dialect used by their assistants. As all languages inevitably varied geographically, so that it is indeed open to argument how far any

The involvement of the Christian churches in issues of language has been central both to the modern linguistic history of sub-Saharan Africa and to the life of the churches themselves. Apart from Swahili in the east and Fulfulde and two or three others in the more Islamized west, none of the languages of sub-Saharan Africa had been given a written form prior to the coming of missionaries.

Early Missionary Translation Work

The earliest extant Bantu text is a lengthy catechism in Portuguese and Kongo produced by the Jesuit Mattheus Cardoso and printed in Lisbon in 1624. This, a subsequent Kongo dictionary by a Capuchin, Georges de Geel, and a grammar produced by another Capuchin, Giacinto Brugiotti da Vetralla in 1659, are immensely valuable for Bantu linguistic history. The last includes the Bantu noun-class and concord system. Unfortunately, the Catholic missionaries of that era produced little work in any other language. It was the 19th-century Protestant missionaries, with their far higher conviction of the necessity of Bible translation, who produced a mass of linguistic work – dictionaries, grammars, and biblical texts for scores of languages in every part of Africa. The pioneering work of Krapf in the east, van der Kemp, Moffat, Appleyard, and Colenso in the south, and Raban, Schön, and Crowther in the west – to name but a few from the early and middle years of the 19th century – stands for a vastly larger undertaking that has as yet received no adequate historical survey. In almost every African language with a written literature, missionaries have been responsible for the basic work and indeed for most subsequent published literature as well, except in a handful of the larger languages. The vast multiplicity of African languages and the policy of most colonial and postcolonial governments to use English, French, or Portuguese for educational purposes mean that (apart from some score of languages, such as Yoruba, Swahili, Shona, and Ganda) there is still little, if anything, of any extent published in most languages except for church purposes.

Missionary Imposition of a Dialect as a Language

Missionaries could not, of course, have done this work without African collaborators who had themselves first learned English. Inevitably the precise language canonized by missionaries, in the first dictionaries and New Testaments, was the dialect used by their assistants. As all languages inevitably varied geographically, so that it is indeed open to argument how far any

specific language actually existed prior to its precise, missionary-constructed form, the language of missionary literature represents in every case the particular local form in which the missionary's assistants were at home. Once a language was printed, it was, however, essential that it be used across a wider area in which people were much less at home with it. The missionary approach had mistakenly assumed a degree of linguistic uniformity that in fact it had rather to impose. This produced inevitable tensions and at times rebellions. Moreover, other missionaries working in the same general language area but some distance away inevitably absorbed different dialectical forms. Missionaries certainly revised their translations as their language knowledge improved, but Africans had also to some extent to relearn their languages when they studied the Scriptures or other works in mission schools. Moreover, tensions between different forms of a language as fixed by a range of different missionary translations (so that, for instance, Protestant and Catholic Baganda could divide linguistically as well as theologically) continued for decades, at least until the 1930s, or later, when colonial governments insisted on standardized forms for state-assisted schools. Even then, imposed uniformity, such as 'Union Igbo,' was not easily accepted.

The missionary preoccupation with the vernacular written word was quickly taken over by leading African Christians. The Reverend John Raban's initial work on Yoruba was continued by the Yoruba school teacher, and later bishop, Samuel Ajayi Crowther, who made a major linguistic contribution in his recognition of the essential role of tone in Yoruba, Nupe, and other Nigerian languages. In southern Africa, the Presbyterian minister Tiyo Soga, the translator of Bunyan's *Pilgrim's progress* into Xhosa, died in 1871 while at work on the Acts of the Apostles. While some missionaries and African Christians, such as Schön and Crowther, were undoubtedly outstanding precisely as students of language, their primary preoccupation – to translate as quickly as possible as much biblical and Christian literature as they could – often, it must be said, weakened their achievement precisely as linguists.

The Name of God

For missionaries, the great question was a practical and pedagogical one: how far could they find suitable words already in existence for the special things they wished to teach about, how far had they instead to invent words in which to do so? In the latter case, how were they to arrive at the words they needed? It is striking that in the large majority of African languages, missionaries were content to use an existing vernacular name for the all-important name of God. In some places, at least at first, they felt unable to do this and imported foreign names like Dio or Godi. But these were exceptional and mostly short-lived. For the greater part, the missionaries became convinced that Africans had already sufficient belief in a single almighty spirit for it to be possible to adopt an African name for such a spirit to use for the biblical and Christian Yahweh, the Father of Jesus. Thus, in East Africa, Mungu, Mulungu, or Ruhanga; in central Africa Lesa or Nzambi; in southern Africa Molimo all came – among many other names – to be used. In Zimbabwe, there were long hesitations among some over the use of Mwari – in this case because of its localized cult. It is noticeable that in many cases these names had already obtained a considerable degree of intertribal currency, in some cases overshadowing more local names. It seems clear that missionaries preferred words with the wider usage.

Other Key Christian Terms

This seems true for a wide range of religious terms. As missionaries advanced from one people to another, they inevitably carried words, especially key words, across intertribal boundaries. They did this particularly in eastern Africa in the early years with regard to Swahili. While Swahili is basically a Bantu language, it has incorporated a very large number of Arabic words, including especially religious words. Despite their Muslim origin, these seemed, with their theistic character and biblical links, ideal for missionary use. Hence words like *eddini, essala, injili, kanisa* ('religion,' 'prayer,' 'gospel,' 'church') were imported into many other inland Bantu languages from Swahili. They seemed to fill a gap while avoiding the importation of purely European words to which many missionaries were driven in other circumstances, when no suitable vernacular word was discovered for some major Christian concept. However, a later generation of missionaries found this dependence upon Swahili regrettable, perhaps because of its apparent Muslim connotations, and in several languages such words were systematically eliminated if alternatives could be found.

'Gospel' and 'baptize' are typical cases. The root meaning of the one is 'good news,' of the other 'wash' or 'sprinkle,' but each has turned in Christian usage almost into a proper name. Many early missionaries (Catholics especially) were unwilling simply to find a vernacular phrase meaning 'good news' or 'wash' and render the words in this way. Hence, vernacular Christian doctrinal texts could be peppered with strange-sounding terms, transliterations of Greek, Latin, or English. The tendency now is to eliminate these in favor of genuinely local words.

Muzimu and *Nganga*

In other cases, traditional words with a religious connotation were available but were avoided just because it seemed the wrong connotation. Words for 'spirit' are probably the clearest case. Missionaries were most anxious not to let the 'Holy Spirit' become identified with, or understood in terms of, the 'spirits' of traditional religion, especially spirits of the dead, which frequently possessed the living. Hence, nearly everywhere the typical Bantu spirit word *muzimu* was rejected. Again, the almost universally used term throughout Bantu Africa for a priest, diviner, or medium, *nganga*, was regarded as unusable for a Christian minister in the 19th century and since. The *nganga* became, instead, the stereotype of the pagan 'witch doctor' against whose influence Christianity was battling. This is interesting because missionaries in the 16th and 17th centuries willingly described themselves as '*nganga*.' These are two cases in which the linguistic challenge of assimilation still remains to be met.

The Fluidity of Word Meanings

What seems clear is that language usage in nonliterate societies is far more fluid than might be imagined. It is less a matter of finding the right word than of making it right by regular usage. Existing words had the flexibility of all language, and anyway missionaries could not know how reliable were their informants. Words (and not only the name of God) moved easily across language groups in precolonial Africa. Missionary importations and adaptations were nothing new. Once a word was adopted, used in a certain way in scriptures, hymns, and sermons, it easily acquired the meaning now given it, whether it had it before or not. Within a generation or so, non-Christians, too, could be using it the missionary way. Thus, for instance, even where missionaries mistakenly adopted for 'God' a local name that had really belonged to a culture hero of quite limited importance (e.g., the Nyakyusa Kyali), the new missionary content for the word quickly became a normative one, recognized by all but the antiquarian.

The Lasting Language Impact of Missionary Translations

In the scores of African languages that have possessed a Bible, a hymn book, a catechism, for 50 to 100 years, but still very little more in the way of written literature, these books, with their specific vocabulary and the meanings of the words that the content of the Bible and Christian tradition impose upon them, may now be near the heart of living language usage. Rather little in that vocabulary was formally imported, but the conversion of traditional words to new meanings has effectively taken place. Nevertheless, the new meanings have not simply obliterated old meanings. African religion in most places is now an integrated mix of the traditional with the Christian (or the Islamic). That mix is one of concept, of ritual, and also, inevitably, of linguistic meaning. Moreover, the process described in this article has not proceeded everywhere at the same rate or gone so far. In some languages it began considerably later than in others. In many smaller languages, little of scripture has even now been printed. Much has depended, too, on how linguistically skilled early missionaries were. In some places they did indeed master the language, translate intelligibly, preach eloquently, and in a way impose their meanings upon it. In others, missionaries were unable to do this. Their linguistic ability was simply inadequate. They preached through poorly trained interpreters and remained so marginal to the vernacular culture that what translations they produced had little impact upon its world of meaning. The very fact that schooling was in English or French might have actually protected vernacular meanings from the impact of Western Christian verbal imperialism. Nevertheless, in most rural areas where Christian churches have been actively at work and (as in the case of most countries of Africa south of the Equator) now have a majority of the population considering itself Christian, biblical literature and a Christian interpretation of religious words may be almost as central to vernacular culture as was the King James version and its vocabulary specific to the culture of preindustrial Britain.

Christianity in Central Asia and the Near East

During the 2nd century A.D., the kingdom of Osrohoene, with its capital city Edessa (Urfa in Turkey), emerged as a major center of Syriac Christianity, which quickly spread throughout the Syrian territories of the east Roman Empire and penetrated Mesopotamia. When the Sassanians conquered the Parthians in 225 A.D., the incoming Zoroastrian king Ardashir found substantial Christian communities in his territories, stretching from the northern regions of Mesopotamia to Mesene (Basra) in southern Iraq. Syriac Christianity also expanded along the coastline of the Arabian Gulf and was transmitted to India, as well as establishing itself in Iran and Central Asia.

The Christian population of the Sassanid Empire were supplemented by deportees from Byzantium following the incursions of Shapur I into Syria in 256 A.D. and 260 A.D. This pattern was repeated throughout the centuries of Sassanid rule. It culminated with the influx of thousands of Monophysite captives following the defeat of Antioch by Chosroes II, whose campaigns ventured deep within the Byzantine empire, taking Jerusalem in 612 A.D. Some of the deportees were settled in Herat in northern Afghanistan, where Syrian Orthodox bishops still resided as late as the 9th century. In Mesopotamia, where the Sassanian royal house and the nobility were Zoroastrian, the burgeoning Christian communities lived alongside Jews, Manichaeans, and Mandaeans.

The Council of Nicaea was convened in 325 A.D. by Emperor Constantine (324–337 A.D.) to discuss the Arian interpretation of the Trinity, resulting in the Niceno-Constantinopolitan Creed of 381 A.D. that was adopted universally by Christian communities in both the Byzantine and Sassanid territories. This unity was shattered at the Council of Ephesus in 431 A.D. when Nestorius, bishop of Constantinople, was excommunicated because of his Diophysite theology. The Church of the East, which followed the teachings of Nestorius, separated from Christianity in the Byzantine territories. In reality, in 424 A.D. the Synod of Dādīšō, held at the religious centre of Hira in southwest Iraq, had declared the Christian communities east of the Euphrates autocephalous of the five pentarchies of Alexandria, Antioch, Constantinople, Jerusalem, and Rome, effectively severing relations with the West.

By the 5th century, the Church of the East had consolidated itself in eastern Iran and Turkestan, although Syrian Orthodox, Armenian, and Byzantine (principally Melkite) missionaries were also active. The *Synodicon Orientale*, a listing of the synods held by the Church of the East between 410 A.D. and 790 A.D., recorded that bishops of Nišapur, Marv, and Herat were represented at the Synod of Dādīšō in 424 A.D. The Syriac *History of Mar Aba* recounts the consecration of a Hephthalite bishop in 549 A.D., when a delegation traveled to Seleucia- Ctesiphon to present their candidate and rendered obeisance both to the Sassanid monarch and the Patriarch. The Hephthalite see may have been the bishopric of Badghis-Qadistan, near Herat. Herat was elevated to a metropolitanate of the Church of the East at the 585 A.D. Synod of Išo'yāb, but, as mentioned, there was also a Syrian Orthodox presence.

Marv, the administrative seat of the Sassanid province of Margiana, was strategically located on the Silk Route to be the starting point for missions in Central Asia among the Turkic nomadic tribes that were progressively moving westward and had infiltrated the regions around the Syr and Amu Darya rivers. Reflecting this role, the Synod of Mar Aba in 544 A.D. ranked Marv as the seventh metropolitanate, after Beth Lapat, Nisibis, Perath dhe Maysan (Basra), Arbel (Erbil), Karkha de Beth Selokh (Kirkuk), and Rew Ardashir, all of which were located in Mesopotamia or the nearby Iranian territories. The missionary activities of the metropolitans of Marv are recorded in several Syriac sources. The anonymous 6th-century *Chronica Minora* narrates that the metropolitan converted a Turkic kinglet by a quasi-shamanic ceremony, making the sign of the cross to still a storm that had been conjured by pagan priests.

Samarkand was also a base for proselytism among both the Sogdian-speaking Iranian communities settled in east Turkestan and the westward-moving nomadic groups whose Turkic languages became the lingua franca. Syriac sources do not comment directly on Samarkand's role in missionary enterprises, but there are three Nestorian crosses and inscriptions engraved on a rock on the main route from Bactria to Lhasa. A single Sogdian word may be interpreted as 'Jesus', while a longer inscription, also written in Sogdian, reads "in the year 210 ... came Nôš-farn from Samarkand as emissary to the Khan of Tibet" (Gillman and Klimkeit, 1999: 108). The metropolitan of Samarkand may have helped consolidate the Church of the East in Tibet where, in the late 8th century, Patriarch Timothy I made reference to the consecration of a metropolitan of the bēt tûptāyê', possibly the Tibetans.

The metropolitanate of Kashgar probably emerged during the dynamic incumbency of Patriarch Timothy I (787/8–823 A.D.). An important trade station, Kashgar was located where the Silk Route to China bifurcated. Its jurisdiction extended over the bishoprics of Yarkand, Urumtsi, and various sites on the rim of the inhospitable Tarim basin, including Khotan. On the northern side, the Turfan oasis was dotted with Christian sites. The most renowned was Buläyiq, where a monastery of the Church of the East and its library of Syriac, Sogdian, and Christian Turkic manuscripts was discovered by the 1905 expedition of Albert von le Coq. Kashgar was still a metropolitanate in the 12th century A.D., while a century later Marco Polo noted that near the city were "some Turks who are Nestorian Christians." The metropolitanate was well located for ministering conversions among the eastern Turco-Mongol Naiman, Merkit, Ongut, and Kerait tribes.

The precise details of the conversions of these tribes are not known, but the influence of Christianity probably was felt during the 9th century when the dioceses of the Church of the East stretched to Chang'an in western China. Gregory Bar Hebræus, writing during the Mongol Il-Khanate, narrated the conversion of the Kerait in 1007 A.D. in his two Syriac historiographies, *Chronicon ecclesiasticum* and *Chronicon Syriacum*, but the term 'Kerait' may have been inserted. Thomas of Marga's *Historia monastica* (Book of the governors), written c. 840 A.D., narrates the preparation undertaken by missionaries, which included instruction in Syriac, the liturgical language of the Church of the East, as well as vernacular languages. Missionaries built churches, baptized, and organized dioceses, selecting the lower ranks of the clergy, priests and deacons, from the indigenous population. Bishops and metropolitans were drawn from Mesopotamian clergy, thus maintaining a direct link with Seleucia-Ctesiphon and later Baghdad.

During the Abbassid period (850–1256 A.D.), Christians assumed a prominent profile as physicians to the caliphs and the transmitters of Greek scientific and medical works. One of the principals of the House of Knowledge, an institution of higher learning in Baghdad founded by Caliph Mamun (d. 833), was the 'Nestorian' Hunain ibn Ishaq (d. 873), who translated over 100 books from Greek into Syriac and Arabic, including Aristotle's *Organum*, *Analyticon,* and *Hermaneutics*. Despite the increasingly Islamic tenor of the law and bureaucracy, financial exactions, and forced conversion of some Christian Arab tribes, Patriarch Timothy I was able to win the respect of Caliph al-Mahdi (775–785 A.D.) by emphasizing the traditional enmity between the Church of the East and the Orthodox church of Byzantium. A staunch defender of the faith, Timothy also debated with the caliph on the respective claims of Christianity and Islam but sought to stress the common monotheism of Muslims and Christians.

The Church of the East reached its zenith during the incumbency of Timothy I. Its dioceses encompassed Arabia, where a bishop was ordained for the communities in Sanaa (Yemen); India, where the church was elevated to a metropolitanate; Tibet; Central Asia; and China. Details are found in Timothy's extant correspondence. Writing to the monks of Mar Maron, he revealed the conversion of "the King of the Turks with all his people." In a letter sent to the Metropolitan of Elam, Timothy announced: "in these days the Spirit anointed a metropolitan for the bēt ṭûrkāyê." This event was also chronicled in Arabic during the 12th century by the Christian historian Mari ibn Suleiman in *Kitab'ul mijdal*: "Henceforth, Timothy led into faith the *Khaqan*, the king of the Turks and other nations." The metropolitanate was probably located near the Syr Darya river in western Turkestan, where the Oghuz settled around 600 A.D. During the incumbency of Timothy I, the T'ang dynasty in China accepted the Church of the East as a 'Persian religion,' together with Manichaeism and Buddhism.

The legacy of the Church of the East's missions in Central Asia came to fruition in 1258 A.D. when Hulagu Khan sacked Baghdad. Several Christian Kerait princesses, including Sorghotani, the mother and wife of Hulugu Khan, were in the royal Mongol household. Gregory Bar Hebræus's *Chronography* notes that in 1279 A.D. the mother of the third Il-Khan, Tegudar Ahmad (1282–1284 A.D.), revived the Christian procession of the Epiphany, which had ceased due to conflicts between the Christians and Muslims. The Il-Khans were disposed to Christianity and considered an alliance with Western Europe against the Muslims, sending the Uighur monk Rabban Sauma to Europe as an ambassador. There he met Philip, king of France, and Edward I of England, as well as Pope Nicholas IV. In 1281 A.D. an Ongut monk, enthroned as Mar Yabhallaha III, became Patriarch of the Church of the East. Ten years later, the Il-Khans embraced Islam and the tide turned against the Christian communities in their domains. The Mongolian script, a derivative of Syriac, is a lasting legacy of the Christian influence.

The Fransciscan friars John de Plan Carpin and William of Rubruck, who visited in the 13th century, provide information about the 'Nestorians' at the Mongol court in Karakorum. These medieval Latin commentaries are the last eyewitness accounts of the Mongol Christians of Central Asia. At Tokmek and Pishpek, in the region of Semireche'e, between

Lake Balkash and Issy-kol (Kirghizia), cemeteries with hundreds of Old Turkic headstones written in the Syriac script indicate the presence of sizeable Christian Turkic communities between the 9th and 14th centuries. Faced with the ravages of Timur Lang, the Christian communities of Central Asia disappeared, and Mesopotamian Christians were forced northward into the Hakkari region of Kurdistan. The Church of the East existed there as an enclave until the end of the Ottoman Empire. The Syrian Orthodox community also survived in pockets around Tekrit in Iraq, in northeast Syria, and in the Tur 'Abdin region of southeast Turkey.

Under Ottoman jurisdiction, the Syriac communities were governed under the 'Millet i-Rum' being granted a degree of semi-independence in return for allegiance to the sultan and payment of taxes. The activities of Roman Catholic missionaries during the 17th and 18th centuries led to the creation of Uniate churches, which seceded from the Church of the East and the Syrian Orthodox. At first the links between the ancient Syriac churches and Rome were tenuous, with many schisms and counterclaims, but the Chaldaeans and the Syrian Catholics were permitted to retain their liturgy and the use of Syriac. An influx of Protestant missionaries arrived in the early 19th century, following the discovery of the ancient Christian communities. The American Presbyterian Mission established its base of Urmia (in Azerbaijan, Iran) in 1830, building schools, hospitals, and welfare centers and establishing the first printing press. The Anglican mission to the Church of the East was led by the Rev. George Percy Badger, who was the representative of the Archbishop of Canterbury. On his two journeys in 1842–1844 and 1850 to the homeland of the Church of the East in Kurdistan, Badger also met Syrian Orthodox communities at Aleppo, Urfa, Diyarbekir, Mardin, and Mosul.

The Uniate churches are now dominant in the Near East, with congregations in Iran, Iraq, Syria, Jordan, and Istanbul. The Chaldaeans are the largest denomination in Iraq, but the ancient churches also survive. Both the Church of the East, otherwise known as Assyrian, and Syrian Orthodox communities are still found in Syria, Iran, and Iraq, with sizeable diaspora communities in Europe, the United States, and Australia.

With the Spanish conquest and the Portuguese settlement of Brazil, Spanish and Portuguese became the principal languages of those two New World empires: Portuguese in Brazil, and Spanish in the rest of South America, Mexico, and large areas of southwestern United States. But European missionaries who followed the conquest used the Native American languages as their main instrument for evangelization. Thanks largely to their efforts, the myriad Indian languages of Latin America were preserved throughout colonial times, and some of them, such as Quechua, Aymara, and Guaraní, continue to be spoken today by millions of Latin Americans. The religious also transformed the oral traditions of the pre-Columbian peoples into written literature in Spanish and Portuguese, as well as the native languages.

Spain and Portugal established Catholic Christianity as the official religion of all Latin America. Under the concept of royal patronage, a special concession made by different popes, the Spanish and Portuguese monarchs enjoyed the right to establish the church, name bishops, collect tithes, and authorize missionaries to go to the New World. The initial evangelization of Spanish and Portuguese America was carried out by missionaries belonging to religious orders: Franciscans, Dominicans, Augustinians, and later on, the Jesuits. The secular or diocesan clergy followed later in order to serve the pastoral needs of the white settlers, although many of them also did mission work among the Indians and black slaves.

The first phase of evangelization, which corresponded to the conquest of the Caribbean and the

With the Spanish conquest and the Portuguese settlement of Brazil, Spanish and Portuguese became the principal languages of those two New World empires: Portuguese in Brazil, and Spanish in the rest of South America, Mexico, and large areas of southwestern United States. But European missionaries who followed the conquest used the Native American languages as their main instrument for evangelization. Thanks largely to their efforts, the myriad Indian languages of Latin America were preserved throughout colonial times, and some of them, such as Quechua, Aymara, and Guaraní, continue to be spoken today by millions of Latin Americans. The religious also transformed the oral traditions of the pre-Columbian peoples into written literature in Spanish and Portuguese, as well as the native languages.

Spain and Portugal established Catholic Christianity as the official religion of all Latin America. Under the concept of royal patronage, a special concession made by different popes, the Spanish and Portuguese monarchs enjoyed the right to establish the church, name bishops, collect tithes, and authorize missionaries to go to the New World. The initial evangelization of Spanish and Portuguese America was carried out by missionaries belonging to religious orders: Franciscans, Dominicans, Augustinians, and later on, the Jesuits. The secular or diocesan clergy followed later in order to serve the pastoral needs of the white settlers, although many of them also did mission work among the Indians and black slaves.

The first phase of evangelization, which corresponded to the conquest of the Caribbean and the

first years of Spanish rule in Mexico, was somewhat disorganized: The missionaries did not know the native languages and practiced mass baptisms without knowing whether the Indians understood them. At the same time, in reaction to the atrocities committed by the European settlers, many churchmen raised their voice in defense of the Indians. Antonio de Montesinos, a Domincan, denounced his fellow Spaniards in a sermon in Santo Domingo in 1511, and soon afterward Bartolomé de las Casas, who originally had gone to the New World to exploit the Indians, experienced a major conversion, became a Dominican, and emerged as champion of the rights of the Indians. He influenced Emperor Charles V, who was simultaneously King of Spain (1516–1556), to make laws to protect the Indians.

Mexico: The Utopian Phase

This first phase was characterized by utopian and even apocalyptic concepts. Many religious dreamed of forging a church in which they and the Indians would live together in peaceable harmony, free from the contamination of European civilization. Vasco de Quiroga, a lay humanist who was a member of the ruling board of Mexico, founded two colonies for the Indians, both based on Thomas More's *Utopia*. The Franciscan bishop of Mexico City, Juan de Zumárraga, founded several schools for Indians boys and girls, the most famous of which was Santa Cruz of Tlatelolco (1536). In time, the missionaries finally began mastering the native languages, usually by having recourse to newly baptized Indians, especially children, many of whom studied in the mission schools. The Franciscan friar Toribio de Benavente (known by his Nahuatl name of Motolinía) wrote a history of the Indians of New Spain (Mexico), and later another Franciscan, Bernardino de Sahagún, with the aid of his own Indian students at Santa Cruz of Tlatelolco, wrote the multivolume *History of the things of New Spain* (finished around 1580) in Nahuatl and Spanish. These early histories were based upon oral testimony and codices that contained pictures and symbolic expressions of Aztec history and culture. The missionaries also wrote grammars, catechisms, and books of sermons in Nahuatl and other native languages. In 1544 Pedro de Córdoba, a Franciscan, published the first catechism printed in Mexico, 'in the Mexican and Castilian Languages.' Between 1524 and 1572, 109 works were written in native languages in Mexico by missionaries, 80 of which were done by Franciscans.

Peru

These same religious orders set about evangelizing Peru following Pizarro's conquest of the Incas in 1532. They founded Indian parishes and wrote grammars and sermons in Quechua, the language that the Incas had used as the lingua franca throughout their empire. In southern Peru and Bolivia the principal language used was Aymara. Viceroy Francisco Toledo (1569–1581) created a system of *reducciones* (territories reserved only for Indians) in order to protect the Indian population from unbridled exploitation by the Spanish. At the same time, the *reducciones* served to control the Indian population and facilitate the process of evangelization. For each *reducción* a parish, known as a *doctrina*, was established.

Methods of Evangelization

Following the Council of Trent (1545–1563), similar church councils were held in Spanish and Portuguese America with the aim of reorganizing the evangelization process and standardizing methods. The Third Lima Council (1582–1583), presided over by Archbishop Toribio de Mogrovejo, produced a catechism. It was the first book printed in Peru, written in three languages: Spanish, Quechua (or Quichua), and Aymara. This catechism was used in Indian parishes until the 18th century throughout the Andes, in Peru, Bolivia, Chile, and Ecuador. Priests who worked in these parishes were expected to preach in the native languages. If they could not, they had recourse to Indian interpreters and catechists. But evangelization was not limited to catechism classes; Christianity was also communicated through the liturgy and sermons, through Biblical plays, and through art and music. In Bolivia and Peru a school of native artists painted images of the Trinity, Christ, Mary, the angels, and many Biblical themes. Popular religiosity in Latin America, which centered on certain devotions, was in large part a creation of the newly Christianized Indians, mestizos, and blacks.

The Jesuits

Arriving early in Brazil (1549), the Jesuits soon became the dominant missionary order there until the 18th century. They arrived later in Spanish America (Peru in 1568; Mexico in 1572), where the other orders had already carried out the initial evangelization. But the Jesuits came for another purpose: to found schools for the Creoles, the sons of the Spanish born in the New World. They also worked with the Indians, but in a

more specialized way than the first religious. For example, in Peru they were entrusted with running two schools in Lima and in Cuzco for the sons of Indian chiefs. José de Acosta, a Spanish Jesuit, wrote two important works: *De procuranda Indorum salute* ('On bringing about the salvation of the Indians,' 1588), which became a standard manual for missionaries on how to treat the Indians; and *A moral and natural history of the Indies* (1590), a wide-ranging description of the religion and cultural achievements of the Peruvian and Mexican Indians. Other Jesuits became notable linguists, especially Alonso de Barzana and Blas Valera. Blas Valera was a mestizo (born of Spanish and Indian blood) who knew Quechua as a child and later as a Jesuit wrote extensively on Inca history and culture. Though most of his writings were lost, they did reach the hands of Garcilaso de la Vega, the Cuzco-born mestizo who wrote the *Royal commentaries of the Incas,* in which he cites Valera extensively. Garcilaso and Blas Valera may be considered among the creators of a distinct American and Peruvian literature because they represented a non-Spanish mentality that esteemed (and at times romanticized) the positive values of Indian culture and history.

For the Jesuits especially, language was the key to evangelization. Particularly important was their mission in Juli, by Lake Titicaca, where they ran four parishes for Indians. Many Jesuits learned Quechua or Aymara in Juli before going to their permanent assignments in Lima, Bolivia, or Chile. Juli also became a connecting link between Lima and the Jesuit missions in Paraguay. Finally, after Charles V, who allowed Flemish friars to work in the New World, the door to foreign (non-Iberian) missionaries was closed. The Jesuits alone had the privilege of having a percentage of foreign missionaries: Germans, Bohemians, Swiss, Italians, Tyroleans (like Eusebius Kino in Arizona), and Flemish.

The Missions

In colonial Latin America, the 'missions' referred to the nomadic and warlike Indians living near the frontiers of the two empires: the deserts of northern Mexico and the Amazon jungle in South America. These Indians had not been touched by the initial conquest and resisted efforts to subdue them until the 17th, 18th, and even the 19th century. But the missionaries were able to do what the soldiers could not: approach the Indians and persuade them to build mission towns. The soldiers followed later in order to protect the missions from non-Christian Indians and the encroachment of other Europeans. The two principal missionary orders were the Franciscans and the Jesuits. Both established missions in California (the Franciscans in present-day California and the Jesuits in Lower California), northern Mexico, remote regions of the Andes (in Peru and Bolivia), the Amazon jungle (in Peru, Bolivia, Ecuador, Colombia, Venezuela, and Brazil), Paraguay, and the Chaco region of Paraguay and Argentina.

Missionaries of both orders learned the new languages and wrote grammars, dictionaries, and catechisms. Gonzalo de Tapia, an exceptionally gifted Jesuit in northern Mexico, was able to give a sermon in Tarascan 15 days after he began studying the language. In Brazil, José de Anchieta, a Portuguese Jesuit, wrote a grammar in Tupí (1556) that became a standard for other missionaries. In the 17th century, another Jesuit, Antonio de Vieira, founded numerous villages to protect the Indians in the Maranhão region of northern Brazil. Vieira exhorted fellow Jesuits to learn the native tongues of the Indians because the Holy Spirit would speak through those new tongues. In Chile, Luis de Valdivia wrote a grammar for the Mapuche language. This intense linguistic activity made it possible for Lorenzo Hervas, the 18th-century Spanish Jesuit philologist, to include a great number of native American languages in his survey of world languages (1784).

Paraguay

Paraguay is the only truly bilingual country of Latin America. This is due in large measure to the Jesuit missionaries, who separated the Guaraní Indians from the white settlers and gathered them into 30 *reducciones* (mission towns), and for over 150 years (1609–1768) spoke to them in their native Guaraní. Before the Jesuits, two Franciscans had prepared the way: Luis de Bolaños, who mastered Guaraní and wrote the first grammar that later missionaries would use, and Francisco Solano, who worked among the tribes in the Argentinian Chaco. The Jesuits themselves created a unified 'mission Guaraní' that became the lingua franca for all the missions. Although the Indians learned a rudimentary Spanish, Guaraní was the principal language used in the missions, which covered present-day southern Paraguay, Uruguay, and the northern department of Argentina, Misiones. Printing presses in the missions produced grammars, dictionaries, and catechisms. The standard grammar used was *Arte de la lengua guaraní* (*Grammar of the Guaraní language,* 1640) by Antonio Ruiz de Montoya, a Peruvian Jesuit who was superior of the missions. Two Jesuits who worked among the Chaco tribes wrote lengthy descriptions of their customs and beliefs: Martin Dobrizhoffer, a Bohemian, and Florian Paucke, a Swiss.

After the expulsion of the Jesuits in 1768, the missions fell into decline. The mission Indians drifted into neighboring Spanish and Portuguese cities, where many used the crafts they had learned in the missions to obtain work. The music played in the mission towns of Chiquitos in eastern Bolivia lives on today, where Baroque music festivals are held yearly.

Creole Authors

In later colonial times, native-born religious made significant contributions to Latin American literature. In Mexico, Sor Juana Inés de la Cruz became the leading poet of America and the only female literary figure of note. The exiled Jesuits, especially Francisco Clavijero of Mexico and Juan Ignacio Molina of Chile, wrote histories of their respective countries that impressed Europeans with the material and cultural wealth of the Indian civilizations of preconquest America.

Contemporary Christianity

Protestantism appeared in the 19th century but only experienced significant growth in the 20th century, especially in Chile, Brazil, and Guatemala. In 1936, William Cameron Townsend founded the Summer Institute of Linguistics with sections in many Latin American countries. Using the Bible as its principal instrument, the Institute aims to convert the languages of the native peoples of the Amazon and other remote areas into written languages. Affiliated to the Wycliffe Bible Translators, based in the United States, the Institute has translated the Bible into numerous native languages. In general, Protestants of the historical confessions and progressive Catholics have achieved a close ecumenical relationship.

Christianity in South Asia

© 2006 Elsevier Ltd. All rights reserved.

Christianity in South Asia has developed in the midst of South Asia's rich historical traditions, diversities of cultural expressions, and multitudes of languages – 1650 or more. It also has faced major religious traditions of Hinduism, Buddhism, and Islam as well as other local religious practices. Interaction with churches and missionaries from the West has been a prime factor in shaping Christianity in this region, but the indigenization of Christian faith in local sociocultural forms by South Asian Christians has played an equally important role in this process.

The Historical Formation of Christianity in South Asia

Three different influxes form the background to Christianity in South Asia: St. Thomas Christianity, Roman Catholic, and Protestant Christianity, and they each form distinctive aspects of South Asian Christianity.

Mar Thoma Christianity

The arrival of the Apostle Thomas in the first century is regarded as the beginning of Christianity in South Asia. Thomas is believed to have arrived on the southwest coast of Malabar by sea, or perhaps came over land from the north, and was later martyred on the southeast coast at Mylapore. Though this tradition lacks material support, nevertheless the existence of Christian and Jewish communities in Malabar can be traced back to the second century. The oldest literature describing the work of St. Thomas is the *Acts of Thomas,* which originated in the second century, as is evidenced by the existence of a Syriac version. Other Christian traders and settlers moved into the western coast of India. Later, as a result of persecutions of Christians in the Persian Empire, there were increasing influxes of Christians to India, and eventually the patriarch of Babylon claimed ecclesiastical authority over these Christians. Syriac became the literary and liturgical language for all Thomas Christians and the doctrine was Nestorian, that is, of the belief that there are two separate natures, divine and human, in Christ (contrary to the Creed of Chalcedon). Though their allegiance was to the Syrian patriarch of Babylon, due to Muslim expansion in the 7th century this close relationship became more difficult to maintain.

In spite of enjoying higher status than other local people, Mar Thoma Christians faced a major challenge when the Portuguese authority established the *Padroado* (royal patronage) in Goa in 1533, and during their subsequent missionary work toward the south. The Syrian Church of the East suffered its major schism in the 19th century, when the Mar Thoma Church of Malabar broke away. Furthermore, as a result of the intervention of outside ecclesiastical authorities, missionary work by other groups, and various internal divisions, there are currently at least six different groups in Kerala who claim their origin in the Thomas tradition.

Catholic Christianity

Catholic Christianity was introduced with the arrival of the Portuguese and the ecclesiastical hierarchy was established in Goa. Through the integration of marriage with the local community and the efforts of monastic priests and friars, the Christian population of Goa increased. The encounters between Roman Catholic and Thomas Christians were long and complicated. They began when the fishermen of Cochin asked help from the authorities in Goa in 1502 to protect them from Muslim threats, which resulted in the acceptance of Roman ecclesiastical authority over the Thomas Christians. However, the relationship between Roman Catholics and Thomas Christians was soured by differences over doctrine and ritual issues and over ecclesiastical hegemony in Kerala. When the *Propaganda Fide* encouraged mission to areas beyond Portuguese control, Catholic missionary activity concentrated on new territories, for example St. Francis Xavier on the Parava coast. Jesuits worked in northwestern Sri Lanka, where they formed the Tamil and Singhala-speaking Christian communities, and in other parts of India, including the areas controlled by the Mughal empire; although some were invited to the court of the Grand Mughal, their work was generally limited in the cultural and diplomatic realm. Most Catholics are of the Latin rite but, following Vatican II, there have been various changes, including the indigenization of liturgy in the local language and the employment of Hindu symbols and philosophy.

Protestant Christianity

Protestant missions began their work with the arrival in 1706 of Lutheran missionaries in Tranquebar, which was a Danish trading port. As a result, the Tamil Evangelical Christian community was established. From 1792 onward, William Carey and other missionaries from England arrived in Serampore, from where the various modes of Protestant mission steadily developed. Some of the East India Company's

chaplains, such as Henry Martyn, were also involved in mission work beyond their role of ministering to the British officials and soldiers and, in fact, many of the company's officers were sympathetic toward missionary work among Indians. One of the distinctive aspects of Protestant missions was their emphasis on the translation of the Bible into local languages. The missionaries in both Tranquebar and Serampore concentrated their efforts in Bible translation, and this had a great impact, not only in terms of the church expansion but also in the indigenization of Christianity in India.

During the late 19th and early 20th centuries the conversion of lower and outcastes in various parts of India brought changes in the demography of the Indian religious setting. Mass conversion along the lines of caste group or community was a general pattern in the history of Christianity in India, but this became a very sensitive issue, especially as the British government in India moved in 1932 to provide a separate electorate for the depressed classes, and it thus became a political issue. Toward Independence there were active discussions for unity among the Protestant denominations in South India, and as a result the Church of South India was formed in 1947 as an amalgamation of the South India United Church, Anglican, and Methodist Churches. This was an unprecedented case of the union of Episcopal and non-Episcopal churches, which became a basis of schemes of union in North India, Pakistan, and Sri Lanka. Furthermore, in 1978 a joint council was established by the Church of South India, Church of North India, and the Mar Thoma Church, reflecting a high degree of union: intercommunion, doctrinal unity, episcopal polity, mutual recognition of one another's ministry, and some joint activities.

Various Christian Expressions and the Demography of Christianity

Christianity was introduced to the northeast of India by the Baptists of Serampore during the early part of the 19th century; they were soon followed by American Baptists and Welsh Presbyterian missionaries during the rest of the 19th and early 20th centuries. Baptist missions were particularly successful in terms of numerical growth, resulting in a remarkably high proportion of Christians in these states (up to 90% in places). The churches in northeast India face considerable challenges in terms of sociopolitical and economic tensions with the central government, but continue to maintain Christian activities both within the northeast and beyond. Recently Pentecostal and charismatic movements, which have conservative theology, organized missionary apparatus, and an emphasis on various spiritual gifts mentioned in the Bible, have been strong among the lower and outcastes, and this seems to set to continue. There has also been movement among *dalit* (outcaste) Christian groups for their social uplift in society as well as equality within the Christian churches.

Christianity in India is the second largest religious minority, after Islam. According to the 2001 census there were 24 million Christians, 2.3% of the total population. Looking at the states, the northeast states have a very high proportion of Christians – for example, Nagaland, 90%; Mizoram, 87%; Meghalaya, 70.3%. Goa has 26.7% and Kerala 19.0% whereas in many of the north and central states Christians are less than 1% of the population. The Christian churches have been actively involved in medical, educational, and other social work in India, for example, the work of Mother Teresa.

Christianity in Sri Lanka largely consists of Catholics who are descendants of converts during the Portuguese time, Anglicans, and some others. Most of the 1.7 million Christians (9.3% of the population) live on the west coast and over 70% are Catholics. Pakistan has 3.8 million Christians (2.4% of the population), of which 80% are from the Punjabi-speaking ethnic group as a result of an early–20th-century mass conversion movement. In 1970 the United Church of Pakistan was formed. In recent years Christians have been the subject of intimidation by some militant Muslim groups. As in other South Asian nations, Christians are a minority in Bangladesh and Nepal, and their religious worship and activities are limited by being in a disadvantageous state in their societies.

Issues in Christianity in South Asia

Christianity in South Asia, with the exception of the Mar Thoma tradition, has been introduced in association with foreign imperial authorities, and this historical attachment has always been a problem for the Christians in this region. There are two major areas of concern for Christianity in South Asia: 'inculturation' of Christianity (making Christianity acceptable and relevant to South Asian culture and society) and overcoming the problem of conversion (the relationship between the Christian community and the wider religious community).

'Inculturation' of Christianity

One of the earliest and best known examples of Christian attempts at inculturation was by the Jesuit missionary Roberto de Nobili, who arrived in Madurai in 1605. He mastered Sanskrit in order

to convey the Christian faith by means of Indian philosophy, and also translated catechisms into the Tamil language. He lived like a *sannyasi* (Hindu holy man) and worked among the Brahmin caste. He even suggested to the Catholic authorities that Sanskrit instead of Latin should be taken as the liturgical language for the Indian church. Since then there have been various attempts to bridge the gap between Christian doctrines and Hindu philosophy by actively employing Sanskritic religious concepts into Christian thinking. In late 19th-century Bengal, Brahmabandhab Upadhyay advocated the idea of Indian Christians as 'Hindu-Catholic' in the sense of being Hindus in culture and Christian in faith, and suggested that the Christian doctrine of the Trinity could be related to the definition of Brahman as Being, Consciousness, and Bliss. Also following classical *advaita* philosophy, in 1964 Raymond Panikkar published his book *The Unknown Christ of Hinduism,* in which he argued that Christ is already present in Hinduism as *Ishvara* (the Lord). On the other hand, following the tradition of *bhaki* devotion, in the early 20th century A. J. Appasamy interpreted Jesus Christ as the unique *Avatar* (descent) or incarnation of the deity.

The Problem of Conversion and Communal Relations

The most contentious issue between Christian and Hindu communities has been the problem of conversion. The traditional understanding of conversion as manifested in joining the Christian community leads to serious difficulties in the life of the converts in South Asia, particularly in India, where change of religious community has major implications for relations with the wider Hindu community. Hindu leaders oppose Christian conversion as incompatible with Indian philosophies and social practices, and have countered it by legislation and by the reconversion of Christian converts. In particular in the 1930s, M. K. Gandhi made his strong objection to Christian conversion activities a part of his political agenda in his struggle against the British Raj because he feared mass conversions would increase communal disturbances. During and after Independence, the discussion about conversion was focused on the inclusion of the freedom to 'propagate' as one of the fundamental rights in the Indian Constitution Assembly (1947–1949). Hindu objections to Christian missionary activities led to a public inquiry into missionary activities by the government of Madhya Pradesh in 1954. The resulting Niyogi Report, completed in 1956, was highly critical of converting activities, particularly the conversion of tribals, and of the activities of foreign missionaries. Subsequently, Hindu objections to conversion were made concrete in three main ways: by the introduction of Hindu 'personal laws,' which were disadvantageous for caste Hindus who converted to another religion (1955–1956); by the limitation of social benefits for converts from Scheduled Caste backgrounds (1950s); and by the passing of the Freedom of Religion Acts in various states (1960s and 1970s). The election of 2003 was won by the Congress Party, which promotes a secular approach to religious issues in the central government, and the tensions over the conversion issue seem to have relaxed.

Christianity in South Asia, despite being a minority in numbers, has made major contributions to nation-building, especially in education, medical work, and other social areas. Christian communities in India try to live side by side with their neighbors by fully integrating into the languages and cultures of India, while at the same time affirming their Christian faith and practices, which may be distinctive from others. The future shape of Christianity in South Asia may lie in the balancing of these two aspects of integration and distinctiveness as Christians strive to exhibit their integrity and identity in both public and private life in the diverse yet often rigid cultures and societies of this region.

Christianity in Southeast Asia

B Watson Andaya, University of Hawai'i, Honolulu, Hawaii

© 2006 Elsevier Ltd. All rights reserved.

The Early Spread of Christianity

The history of Christianity in Southeast Asia can be dated from 1494, when the Treaty of Tordesillas divided the global missionary project between Europe's two great Catholic powers. What is now the Philippines fell in the Spanish sphere, with the Portuguese given responsibility for the Malay-Indonesian archipelago. A Spanish expedition reached the Philippines in 1521, but a full commitment did not come until 1570, when Manila was captured. Over the next century Spanish control and the Christian religion spread over the entire archipelago except for the Muslim south.

From the outset, the Catholic orders were committed to mastering local languages. Using romanized phonetic writing rather than local scripts, they compiled dictionaries, catechisms, confessions, and sermons in the major Filipino languages. Latin or Castilian words were retained for terms such as 'God,' 'heaven,' 'hell,' 'holy spirit,' 'sin,' 'limbo,' etc., so that new concepts would not carry the baggage of animist beliefs. The vocabulary and traditions of Christianity were also adapted by Southeast Asians, with Filipino versions of the sung *Pasyon*, the life of Christ, assuming a central position in religious ritual. Though Church schools were a major vehicle for imparting the new teachings, ethnolinguistic boundaries were reinforced because each order developed expertise in the cultural area to which it was assigned.

The impact of Portugal's Christianizing effort was more limited than that of Spain. The conquest of Melaka on the Malay Peninsula in 1511 was expected to provide a base for missionary work, but Islam was already entrenched in the western archipelago. There was less opposition in the islands east of Java, but despite initial successes the lack of priests made it difficult to prevent apostasy. Numerous Portuguese words were nonetheless adopted into local languages and Portuguese became widely used in diplomacy and trade. The creole known as Kristang is still spoken by the Portuguese-descended community in Melaka.

The Portuguese missionary effort suffered a major blow when the Dutch East India Company (VOC) captured Melaka in 1641. The Dutch harbored an intense dislike of Papism and actively promoted Protestantism, especially in the spice-producing islands of eastern Indonesia where VOC interests were concentrated. VOC ministers used Portuguese or more commonly Malay for Christian instruction, since both were well established as lingua franca. The Bible was printed in both romanized Malay and the Arabic-based Jawi script. Christian teachings were prominent in the schools established in areas under VOC control, with teaching delegated to Christian schoolmasters familiar with Malay in its new romanized form. Although older Catholic communities such as the one in Melaka survived, Portuguese missionary activity was mostly restricted to coastal areas in Flores and eastern Timor. The British settlements of Penang (1786) and Singapore (1819), intended primarily to further trade, had only limited influence in Christian proselytizing.

In mainland Southeast Asia, Catholic missions were more active. A romanized form of Vietnamese known as *quoc ngu* ('national language') was developed to help missionaries prepare sermons and translate texts. In 1662, the Missions Étrangères de Paris (MEP) established a base in Siam, but their 'converts' were generally infants, the dying, or marginalized groups such as the Mon or Lao. The MEP had more success in neighboring Vietnam, especially among women, but suffered periodic persecution, and during the 18th century missionaries were expelled or withdrew.

Christianity, Colonialism and Nationalism

During the 19th century, all Southeast Asia except Thailand came under European control. Colonial administrations typically used a European and a selected local language for administrative purposes, but always showed a preference for employing Christians. Roman Catholicism thus revived in French-controlled Vietnam, and French became the language of the elite. *Quoc ngu* was promoted and eventually displaced Chinese and the Chinese-based Vietnamese script known as *nom*. French-speaking Vietnamese were also employed in Laos and Cambodia. In the Netherlands Indies, Malay was the medium of communication between colonial officials and indigenous administrators, although English was somewhat more common in British Malaya. Because Burma was part of British India, Indians fluent in English were commonly hired for the colonial service, and Burmese never developed into an administrative language.

Colonial administrations were generally wary of encouraging Christian missions in societies already committed to other world religions. However, remote areas were opened up to missionaries, who saw the

compilation of dictionaries and grammars for unwritten and little-known languages as a primary task. New as well, revised translations of the Bible and other Christian books were accorded a high priority. Fonts were developed to print the gospels, Christian tracts, and catechisms in Burmese and Thai characters. In 1813, American Baptist missionaries began working in Burma, concentrating on non-Buddhist societies such as the Chins, Karens, and Kachins. The Netherlands East Indies government looked favorably on the Bible Society and other missionary groups because conversion of animist groups was seen as a way of stemming the Muslim advance. From the mid-19th century, Catholic missions were permitted entry, with German Lutherans prominent among the Toba Batak of Sumatra. In Vietnam the French 'civilizing mission' encouraged Church penetration into the highlands, and in 1917 the first extensive dictionary of a Miao dialect was published.

This linguistic codification had far-reaching effects because the standardized form of favored languages was endorsed by government usage, mission education, school texts, and vernacular newspapers. While this affirmed the position of well-known languages such as Malay, others such as Iban became more widely known as a medium for mission teaching. Tetun Prasa (one of 16 languages in Portuguese Timor) became a lingua franca primarily because it was promoted by the Catholic Church. Often a new sense of identity was forged between previously separate groups, as in the Kachin areas, where Baptist missionaries created a common language, Jinghpaw, for all the Kachin tribes.

For the most part, indigenous Christian communities saw themselves as allies of colonial regimes, and it is not surprising that migrant Asians, especially Chinese, frequently adopted Christianity. In the Philippines, however, the tensions associated with colonialism were fueled because the Catholic Church never welcomed the ordination of indigenous priests. The vocabulary of the *Pasyon*, with its images of heaven, illumination, and saintly leadership, proved highly effective in motivating and inspiring peasant-based anticolonial movements. Resistance also drew on a growing body of nationalist literature written in Spanish by elite Filipinos, the most notable of whom was Dr. Jose Rizal. When a revolution against Spanish rule finally erupted in 1896, he was condemned as a traitor and executed.

With America's acquisition of the Philippines in 1898 after the Spanish-American war, the Catholic Church lost some of its former wealth, but it remained a formidable influence in Philippine society. However, the door was now open to Protestant missionary activity, notably in the highlands and in the Muslim island of Mindanao. English became the accepted medium for Christian preaching and instruction among a new generation of Protestant and Catholic leaders. Tagalog was more common in a Catholic breakaway group, the Iglesia Filipina Independiente, and in the Protestant Iglesia ni Kristo, both of which developed during the early years of the American occupation.

The outbreak of the Second World War and the Japanese invasion of Southeast Asia in 1941 mark the end of a chapter. All Europeans were imprisoned, and although the French gained a short reprieve in Vietnam, the Japanese eventually assumed control here as well. Those who followed Christianity were regarded as supporters of the colonial powers, and European languages were forbidden.

Christianity After Independence

All the colonized countries of Southeast Asia eventually attained their independence after the Second World War, and indigenous control over practice and policy has increased as more local men and women have become ministers, priests, and high-ranking church officials. In 1960, for instance, the first Filipino cardinal was appointed. Although foreign missionaries have continued to work in the region, despite occasional government opposition, there have been pronounced linguistic shifts. In Catholic areas, this was especially evident after Vatican II (1962–1965) sanctioned indigenous languages for celebrating Mass. Within the formal church structure, some developments are uniquely local. In the Philippines, the Pentecostal movement known as El Shaddai has remained within the Catholic Church, but its charismatic leadership, belief in miracles, and use of symbols invoke earlier peasant movements. Because preaching is largely in Tagalog rather than English or the 'Taglish' associated with intellectuals, El Shaddai has a strong working class base and has moved overseas via the Filipino diaspora. At the same time, evangelical churches in the Philippines have also proliferated, drawing many adherents away from mainstream Catholicism.

In Indonesia and Malaysia, most churches still display their origins in European missionizing, but there is considerable room for local transformations because they were initially built on an ethnic base, such as the Gereja Batak Karo Protestan (the Karo Batak Protestant Church) and the Gereja Toraja, both founded in 1941. This allows for local expressions of Christian identity such as the huge monuments that Toba Bataks erect in honor of the dead. After 1965, when communism was made illegal, Church

membership increased everywhere in Indonesia. Because Indonesian rather than a regional language is increasingly common in city churches and among a younger generation of Christians, earlier ethnic explicitness has been muted. An example of a greater inclusiveness comes from Borneo, where the Sidang Injil Borneo (Borneo Gospel Council, established by Westerners in 1928) is now under complete local control. It is very strong among some interior communities such as the Kelabit, but has also established a firm base in urban centers by conducting services in both Malay and Iban. Annual pilgrimages to revered mountain sites, faith healing, and a belief in miracles are all reminiscent of older animist practices. As elsewhere in Southeast Asia, this localization can generate tensions. While there are few difficulties in employing indigenous languages, questions always arise about the adoption of specific cultural practices, especially in regard to marriage and burial.

Throughout contemporary Southeast Asia, connections with overseas Christian organizations remain influential. Because the region is so linguistically diverse, translation of Christian texts is a high priority. In 1971, the Summer Institute of Linguistics was established to translate the Bible into little-known languages. It has been very active in Indonesia, where Catholicism and Protestantism are two of the five officially sanctioned religions and where missionary work is thought to assist development programs. The Indonesian government has permitted numerous Christian missions to teach and proselytize, with most using Indonesian as a medium. In the Philippines, evangelization has also continued in Mindanao, and among interior groups. Apart from Thailand, where the presence of missionaries as teachers and health workers among the hill tribes is again seen as compatible with the government's goal of modernization, Christian proselytization on the mainland has faced more obstacles because there is always the potential that Christian churches will become critics of the government. The authorities have only to look towards East Timor, which was invaded by Indonesia in 1975 and where the Catholic Church emerged as a focus for dissent, particularly after 1981 when Mass was conducted in Tetun Prasa in place of the banned Portuguese. In Burma, ethnic groups associated with Christianity such as the Karens have also been strong opponents of the government. Such examples explain why Christian congregations in Vietnam are subject to closer surveillance, especially in the non-Vietnamese highlands. In the Philippines, the Catholic Church initially supported President Ferdinand Marcos in his declaration of Martial Law in 1972, but Church leadership was critical in the 'people's power' movement that ended the Marcos regime. Much of this opposition was generated by activist priests, nuns, and laity, who argued that liberation theology and an alliance with the Communist Party was the best means for dealing with entrenched poverty. For the most part, this left wing movement has been retained within the Catholic Church.

At the beginning of the 21st century, a disturbing development is the simmering Christian-Muslim hostility in eastern Indonesia and the southern Philippines. Although the issues must be analyzed within a historical context, hostilities have been fueled by global developments. Internet sites have become a battleground as advocates from both sides seek to make their causes more widely known, mostly in English, but also in local languages.

Despite some internal divisions, Christianity maintains an unassailable position in the Philippines (91% of the population) and East Timor (93%), with the majority Roman Catholic. In all the other countries of Southeast Asia, Christians are a minority, ranging from an estimated 10% in Brunei and 8% in Indonesia to 4% in Burma and 0.5% in Thailand. In these places, Christianity is more vulnerable if it is thought to provide an umbrella for opposition to government policies.

Christianity in the Far East

B Vermander, Taipei Ricci Institute, Taipei, Taiwan, ROC

© 2006 Elsevier Ltd. All rights reserved.

The encounter between Christianity and East Asian languages, cultures, and nations took place mainly in the larger context of the confrontation between Western expansionism and societies meeting with a number of crises. The original conditions of the encounter still partly determine the relationship between Christianity and East Asian languages (the focus of this article being on Chinese, Japanese, and Korean). However, this relationship was shaped not by historical factors only but also by the intrinsic difficulties encountered in translating the Christian worldview as elaborated in Europe throughout centuries with words, concepts, and linguistic structures proper to East Asia. Four successive questions will help us to circumscribe the issues here at stake:

- How were the historical circumstances of the encounter between Christianity and East Asia reflected in religious terminology and linguistic choices made up to the present day?
- How did translations of the Bible in East Asian languages contribute to this religious–linguistic encounter?
- How to translate religious terms and concepts dependent on Greco-Latin vocabulary and philosophy into languages of the Far East, especially when taking into account the fact that these languages rely on the present use or past inheritance of Chinese characters loaded with specific cultural meanings?
- Do lexical, syntactic, and cultural characteristics of East Asian languages provide Christianity with new resources for expressing anew its dogma, worldview, and spiritual experience?

Historical Encounter and Language Issues

Christianity as shaped by European tradition encountered the civilizations of Japan, China, and Korea from 1550 on. Until the beginning of the 19th century, East Asian nations witnessed the arrival of mostly Catholic missionaries, whose lingua franca was Latin, although Portuguese (due to the patronage delegated by the Pope to the King of Portugal) and other European languages were also used as communication and translation tools. Protestant missionaries arrived in the region at the beginning of the 19th century. Their linguistic policies had much to do with efforts developed for translating the Bible into vernacular languages and will therefore be sketched later.

Jesuit missionaries in particular dealt directly with a variety of linguistic problems. Matteo Ricci (in China from 1583 until his death in 1610) took pains to write his apologetic works in elegant literary Chinese. In 1615, the Jesuits received from the Pope permission to use vernacular language in the liturgy and to translate the Bible into classical Chinese. However, the development of the Rites Controversy prevented them from making use of this permission. Attempts made in Japan during the same period were also aborted. More generally, although apologetic and catechetical treaties in East Asian languages were numerous, the authoritative sources of Catholicism were still controlled by the use of Latin until the middle of the 20th century. Making use of Chinese as a language for theological teaching and research is a quite recent enterprise, at least when one speaks about 'professional' theologians contrasted with the lay persons who, from the 17th century on, expressed their understanding of the faith in their own language. For example, the Jesuit faculty of theology in Shanghai, which was first transferred to the Philippines from 1952 to 1967, kept Latin as the only teaching language until 1964, later shifting to English. In the Catholic world, it is only with the foundation of the Fu Jen Faculty of Theology, in Taipei, that teaching and research were conducted in Chinese, starting in 1968. From that time on, the shift has been swift and complete. Similar remarks could be made for Japan and Korea. It is no wonder that the Catholic Japanese novelist Shusaku Endo made one of his characters declare to a Christian having studied abroad, "Your Latin is good. But your faith is rotten."

Matteo Ricci (in China from 1583 until his death in 1610) took pains to write his apologetic works in elegant literary Chinese. In 1615, the Jesuits received from the Pope permission to use vernacular language in the liturgy and to translate the Bible into classical Chinese. However, the development of the Rites Controversy prevented them from making use of this permission. Attempts made in Japan during the same period were also aborted. More generally, although apologetic and catechetical treaties in East Asian languages were numerous, the authoritative sources of Catholicism were still controlled by the use of Latin until the middle of the 20th century. Making use of Chinese as a language for theological teaching and research is a quite recent enterprise, at least when one speaks about 'professional' theologians contrasted with the lay persons who, from the 17th century on, expressed their understanding of the faith in their own language. For example, the Jesuit faculty of theology in Shanghai, which was first transferred to the Philippines from 1952 to 1967, kept Latin as the only teaching language until 1964, later shifting to English. In the Catholic world, it is only with the foundation of the Fu Jen Faculty of Theology, in Taipei, that teaching and research were conducted in Chinese, starting in 1968. From that time on, the shift has been swift and complete. Similar remarks could be made for Japan and Korea. It is no wonder that the Catholic Japanese novelist Shusaku Endo made one of his characters declare to a Christian having studied abroad, "Your Latin is good. But your faith is rotten."

Besides the large-scale encounter between European Christianity and East Asia that occurred from 1550 onward, more limited exchanges took place throughout history, which brought into East Asia Christian traditions shaped through other languages and cultures. The most interesting of these attempts is the one that developed after 635 when a few monks from the Chaldean (Nestorian) Church arrived at Xi'an, capital of the Chinese Empire. The Xi'an Stele (erected in 781) remains the most complete testimony of this early presentation of Christianity to China. Based on Syriac documents translated into Chinese, it makes a creative use of Buddhist and Taoist terminology in order to express aspects of the Christian mysteries. Approximately 70 years after the completion of the stele, this Christian community was included within the large-scale persecution that decimated Buddhism in China, and its fragile roots were probably extirpated from the Chinese soil. However, the questions that this first attempt at inculturation raised have remained acute.

With regard to the relationship between the spreading of the faith and sociolinguistics, the cases of Korea and Taiwan deserve special mention. In Korea, Christian use of the Hangul script enabled the spreading of the faith. As early as the end of the 18th century, portions of the Gospels, doctrinal books, and a hymnary appeared in this script. This was a challenge to the perceived cultural superiority of Chinese and a factor in the rise of literacy. In Taiwan, the influence of the Presbyterian Church is strongly linked to its early advocacy of the Taiwanese (Minnan) language and romanization.

Translating the Bible into East Asian Languages

Protestant missionaries in the Far East viewed the encounter between Christianity and Eastern languages mainly through the prism of Bible translation. An exploratory stage took place from 1820 to 1890, a time during which full translations in Japanese and Chinese of both testaments were completed. In approximately 1910–1920, revised, reliable, and well-polished translations of the Bible in Far Eastern languages were published and are still in use today. In 1919, the publication of the Mandarin Union Version, coinciding with the May Fourth Movement, was a lasting cultural and literary event. In Japan, authoritative Catholic and Protestant versions of the New Testament were published in approximately 1910–1917. From the 1920s onward, the translated Bible was not only a religious but also a literary text influencing the intellectual life of China, Korea, and Japan. Biblical narratives and stylistic features entered into Far Eastern languages. After 1960, new publications appeared, based on renewed scholarship. The first complete Chinese Catholic Bible was published in 1967 in Taiwan. In Korea, the Bible was newly translated for common use by both the Catholic and the Protestant churches – the New Testament in 1971 and the Old Testament in 1977. Questions regarding the reliability of these two translations have been raised; a Catholic Bible was completed only in 2002.

East Asian Languages and Christian Dogmas

East Asian Christian theology might have yet to develop a body of assumptions and research that would make it comparable in size and importance to other 'regional' theologies such as found in India, Africa, or Latin America. Furthermore, with regard to the global theological field, Chinese, Korean, and Japanese are still minority, if not marginal, languages.

At the same time, regarding elaborate theological discourse in East Asian languages, the reference to Chinese is somehow analogous to what was the reference to Latin in classical Christianity. Linguistic–cultural concepts embodied in characters such as dao (the Way), li (Reason), and xing (Nature) are the indispensable tools used not only by Chinese but also by Japanese and Korean Christian thinkers. The challenge is that the Chinese intellectual tradition (at the same time a corpus of wisdom, a philosophical worldview, and a religious way of life) does not easily accommodate the conceptual framework through which Christian theology is currently expressed.

Chinese as a linguistic tool deeply differs from languages such as Greek, Latin, or Sanskrit. Its morphology does not distinguish between clear-cut grammatical categories. On the other hand, Chinese characters have a concrete flavor and a suggestiveness of their own and constitute a framework for expressing perception and thought that closely associates form and meaning. Consequently, basic Western concepts such as soul, substance, and modality have often been translated in a rather clumsy way, whereas finding equivalents for some basic Chinese categories is a painstaking endeavor. Furthermore, Chinese terminology is rooted in the canon of classical writings that constituted the basis for the development of Chinese culture and philosophy. This explains the fact that in the entire East Asia, for Christian theology, Confucianism was always perceived as an "embedded cultural–linguistic matrix" (the expression is due to the Protestant Korean theologian Heup Young Kim). With regard to such an inheritance, it is not surprising that theological inculturation has much to do with semantics. In this respect, a few terms deserve special attention.

First, the word 'God' has no immediate equivalent in Chinese language. A choice had to be made between the terms 'Heaven' (*tian*) and 'Lord (or Emperor) from above' (*shangdi*). Forming a pure neologism (as had been the case in Japan), expressions such as 'Supreme Principle' (*taiji*) or 'Spirit' (*shen*) were less plausible alternatives. Later, the Catholics adopted the term *tianzhu* ('Lord of Heaven'), and the ecclesiastical authorities prohibited the use of other names after 1704. Today, most Protestant denominations still prefer the term *shangdi*, which is more common in Chinese.

Another field open for semantic inculturation is that formed by words such as 'virtue' (*daode*), 'law' (*fa*), and 'rites' (*li*). Virtue is traditionally seen as an internal principle that governs one's conduct and deeply influences one's surroundings. In contrast, law is often accused of being an artificial construct that goes against the natural and virtuous flow of life. Some Chinese theologians have contrasted Moses, who gives his people a law, with Confucius, who gives the Chinese cultural world a set of internal principles of conduct.

The previous examples illustrate how terminological problems are intrinsically linked with theological debates that determine the understanding and development of Christianity in East Asian societies and cultures.

East Asian Languages and the Reshaping of the Christian Narrative

During the past 30 years of the 20th century, Korean *minjung* theology has provided East Asia with an example of the importance of language issues in the crafting of a new Christian expression. Although *minjung* roughly means 'people,' the word is usually not translated in order to preserve the specificity of the historical experience it represents. Korean minjung theology pioneered extratextual hermeneutics, insisting on popular rituals and expressions of feeling as a source of inspiration. Of special importance has been the stress put on *kut*, a shaman-like rite that makes the community as a whole gathering, resurrecting and offering sacrifice. Similarly, much writing has been devoted to *han*, the dominant popular feeling arising from "the suppressed, amassed, and condensed experience of oppression" (Suh Nan-dong). Such journey allowed, for instance, the Korean feminist Chung Hyun Kyung to write, "I discovered my bowels are shamanistic bowels, my heart is a Buddhist heart, and my head is a Christian head." (On the blurring of religious identities, *see* **Christianity in Southeast Asia**.) Although not as vibrant as was the case in the 1980s, minjung theology still provides a set of questions for East Asian Christianity as a whole.

The linguistic and cultural rooting of Christianity in the East Asian context is a multivalent endeavor. It means coming to terms with the East Asian worldview embedded into words, concepts, and linguistic structures. It requires to remain open to the plurality of experiences as translated into linguistic forms. The various texts and cultural–linguistic expressions that East Asian Christian thinkers have to deal with are to be taken and analyzed according to their hermeneutical status: A closer look at the ambivalence of Chinese classics enriches biblical exegesis, individual narrations of the spiritual experiences undergone in East Asian contexts challenge Western categories of the spiritual or mystic path, and Buddhist and Taoist scriptures obey hermeneutic models that challenge the usual categorization of theological discourse (a good example is provided by the debate between the Buddhist philosopher Masao Abe and the Catholic theologian David Tracy). Interpreting anew the quest for 'harmony' typical of East Asian culture, recalling stories of hardships, traumas, forgiveness, survival, and hopes, and being attentive to the style of storytelling found in various East Asian cultures, all contribute to the writing of the Christian East Asian narrative. The appropriation of Christianity by East Asian languages is not a mere lexicographic endeavor: words and concepts take blood and flesh within the flow of a story told in many tongues.

Latin Christianity

Christianity first developed in the West in Greek-speaking Jewish communities, thus the earliest surviving documents are in Greek; from the first half of the 3rd century, however, there are sophisticated Latin texts from Christian communities in Africa and in Rome (although use of Greek as well continued in Rome (see Lafferty, 2003)). The religious idiom of the Latin texts owed much to the Greek Christian authors who had built on the linguistic achievements of Hellenistic Judaism (see Loi, 1992a, 1992b), and owed much as well to the anonymous translations of the scriptures from Greek into Latin (known collectively as the *Vetus Latina*, by way of distinction from translations and revisions made later by the biblical scholar Jerome (d. 420)). The Latin of these translations is quite distinctive due to the large number of lexicographic, syntactic, and stylistic Grecisms and mediated Hebraisms created by the literalism of the translators, and due as well to the many vulgarisms (some coincident with Grecisms and Hebraisms) that the translators admitted to the written register, whether consciously, with a view to accessibility, or unconsciously, because of their limited control of written Latin (see Sheerin, 1996a).

Christian Latin

Christian Latin has been studied extensively (see Sanders and Van Uytfanghe, 1989) and its peculiar features are well known (see Sheerin, 1996a). There are mostly literary remains, but the language of less educated Christians is known from inscriptions and graffiti, from reports by literary figures, and from usage in the many sermons that survive from stenographic records. What has proved controversial is the exact linguistic category into which 'Christian Latin' should be placed.

Christian Latin could be called a sociolect, but not as conventionally understood, for its use was not restricted along class lines. Yet it was at once the creation and the linguistic identifier of a particular group, and might even be called a 'restricted code' (in the sense of sociolinguistic scholar Basil Bernstein), for it would have been confusing and exclusionary to non-Christians. But it was employed only in connection with religion, thus it was, in effect, a *Fachsprache*, a 'language for special purposes,' or technolect. However, Christian Latin was employed by and helped to define an ever-growing and more varied community, a community that went far toward realizing its ambition of universality.

The Christian Latin community developed its own terminology through loanwords from Greek and Hebrew, neologisms, and polysemous use of common terms as technical terms. Writers from late antiquity through the early modern period have shown an awareness of the difference and peculiarity of Christian terminology, as when Isidore of Seville (d. 636) contrasted Christian Grecisms to standard Latin terms: "On prophets. Those that the pagans call *vates*, our people call *prophetae* …", "*Martyres* in the Greek language are called *testes* (witnesses) in Latin …" (*Etymologiae* 7: 8.1, 11.1), and Erasmus provided a very comical (and satirical) specimen of an attempt to present Christian discourse in Ciceronian Latin (*Ciceronianus*, Amsterdam edition of Erasmus's *Opera omnia* (ASD) I-2: 640–642; Leyden edition (LB) 1: 995–996).

Phonology and morphology were unaffected save by the many foreign-sounding terms and names

Latin Christianity

Christianity first developed in the West in Greek-speaking Jewish communities, thus the earliest surviving documents are in Greek; from the first half of the 3rd century, however, there are sophisticated Latin texts from Christian communities in Africa and in Rome (although use of Greek as well continued in Rome (see Lafferty, 2003)). The religious idiom of the Latin texts owed much to the Greek Christian authors who had built on the linguistic achievements of Hellenistic Judaism (see Loi, 1992a, 1992b), and owed much as well to the anonymous translations of the scriptures from Greek into Latin (known collectively as the *Vetus Latina*, by way of distinction from translations and revisions made later by the biblical scholar Jerome (d. 420)). The Latin of these translations is quite distinctive due to the large number of lexicographic, syntactic, and stylistic Grecisms and mediated Hebraisms created by the literalism of the translators, and due as well to the many vulgarisms (some coincident with Grecisms and Hebraisms) that the translators admitted to the written register, whether consciously, with a view to accessibility, or unconsciously, because of their limited control of written Latin (see Sheerin, 1996a).

Christian Latin

Christian Latin has been studied extensively (see Sanders and Van Uytfanghe, 1989) and its peculiar features are well known (see Sheerin, 1996a). There are mostly literary remains, but the language of less educated Christians is known from inscriptions and graffiti, from reports by literary figures, and from usage in the many sermons that survive from stenographic records. What has proved controversial is the exact linguistic category into which 'Christian Latin' should be placed.

Christian Latin could be called a sociolect, but not as conventionally understood, for its use was not restricted along class lines. Yet it was at once the creation and the linguistic identifier of a particular group, and might even be called a 'restricted code' (in the sense of sociolinguistic scholar Basil Bernstein), for it would have been confusing and exclusionary to non-Christians. But it was employed only in connection with religion, thus it was, in effect, a *Fachsprache*, a 'language for special purposes,' or technolect. However, Christian Latin was employed by and helped to define an ever-growing and more varied community, a community that went far toward realizing its ambition of universality.

The Christian Latin community developed its own terminology through loanwords from Greek and Hebrew, neologisms, and polysemous use of common terms as technical terms. Writers from late antiquity through the early modern period have shown an awareness of the difference and peculiarity of Christian terminology, as when Isidore of Seville (d. 636) contrasted Christian Grecisms to standard Latin terms: "On prophets. Those that the pagans call *vates*, our people call *prophetae* …", "*Martyres* in the Greek language are called *testes* (witnesses) in Latin …" (*Etymologiae* 7: 8.1, 11.1), and Erasmus provided a very comical (and satirical) specimen of an attempt to present Christian discourse in Ciceronian Latin (*Ciceronianus*, Amsterdam edition of Erasmus's *Opera omnia* (ASD) I-2: 640–642; Leyden edition (LB) 1: 995–996).

Phonology and morphology were unaffected save by the many foreign-sounding terms and names

that came with Christianity and by a toleration of – indeed, a preference for – vulgarisms (see, e.g., Augustine, *De doctrina christiana* IV). Syntax was not greatly affected save that the prestige of the scriptures made written registers of Christian Latin permeable to the Grecisms, mediated Hebraisms, and vulgarisms that characterize the Latin biblical translations. Rusticity became for a time the Christian ideal – often real, sometimes pretended as a humility *topos*.

The Latin Church

Latin became the official language of Western Christianity, so much so that Western Christianity was sometimes called *Latinitas* (see Sheerin, 1987). Latin dominance in Romanized regions is to be expected, but Latin primacy was also resolutely maintained against non-Romance vernacular alternatives. Thus, although Eastern Christianity early produced scripture, liturgy, and literature in Greek, Syriac, Coptic, Ge'ez, Armenian, and Georgian, and later in Church Slavonic and Arabic, Latin remained the unique vehicle for the higher end of ecclesiastical discourse in the West, the official language of the Bible and liturgy (see Sheerin, 1996b), and over the centuries distinctive styles and idioms developed in the schools for philosophy, theology, and canon law (see articles in Mantello and Rigg (1996)). Even when religious texts became available in the vernaculars, a kind of ecclesiastical diglossia continued through the Middle Ages and well beyond (see 'The "Latin Stronghold": the Church,' in Waquet (2001: chap. 2)).

Of course, vernacular vocabulary, syntax, and, to a far greater degree, pronunciation affected ecclesiastical Latin (see Erasmus, *De correcta latini graecique sermonis pronuntiatione*). Not until the early 20th century did anything like a 'standard' pronunciation of ecclesiastical Latin came about, with the general adoption of 'Roman' or 'Italian' pronunciation as a consequence of the revival of Gregorian chant, and even then not without resistance from traditionalists in France (see Brittain, 1955) and, later, from 'nationalists' in Spain. But even in the post-Vatican II era, Latin has remained the official language of the Roman Catholic Church (see the Vatican's official publication, *Acta apostolicae sedis*). How well Latin has served may be seen in the fact that for 1700 years Latin has been the vehicle of administration, regulation, and education of a polyglot religious *imperium* more extensive than any political empire the world has seen.

Clerical education had to begin with training in Latin. Even in late antiquity, clerical ignorance of Latin was a problem; Augustine (*De catechizandis rudibus* 9.13) remarked on the scandal caused by clerics' garbled Latin, and clerical inability to compose *ex tempore* contributed to the abandonment of improvised liturgical prayers for fixed ones. Complaints about clerical ignorance of Latin are found in the literature through the Middle Ages and well beyond (see Waquet, 2001: 60–63). Training in Latin, rudimentary or advanced, was the preserve of males, of clergy alone for centuries, but later young 'gentlemen' as well (see Ong, 1959). Though some women, mostly in religious life, were taught Latin and became proficient scribes and composers of Latin texts (see Churchill *et al.*, 2002), women in religious life, in degree varying with time and place, had to depend on oral instruction in the vernacular or on versions of theological and spiritual texts in the vernacular.

The vernacular languages of the Catholic peoples, however, were the medium for unwritten communication with the vast majority who did not know Latin. In the later Middle Ages, multiple factors evoked an increase in the composition of religious texts in the vernacular languages and *pari passu* an elaboration of vernacular resources for the presentation of religious thought (a view of these resources can be had in a glance at the work of Foster and Carey (2002)). Printing, the Reformation, and the Counter-reformation accelerated the vernacularization of religious language. But the Catholic church barely allowed vernacular translations of the Latin Vulgate Bible and refused translation of the Latin liturgy. Latin remained the medium for theological education and discourse, but vernacular theological language had to be employed in vernacular controversial literature and in vernacular catechisms for the instruction of the laity.

The Roman Catholic Church in the United States

Here focus shifts abruptly from the pre-modern to the modern period, and narrows from the official Latin language to the vernacular of American Catholics. Until at least the early 1960s, the speech of American Catholics was characterized, to a limited degree, by pronunciation and the use of Latin tags (for their residue, see Wills (1972: 16–17) and Bretzke (1998)), but far more by a latinate English terminology, a technolect, largely derived from the *Baltimore catechism*, which had been promulgated by the U.S. Catholic bishops in 1891 (the American equivalent of the Anglo-Irish 'penny catechism,' *A catechism of Christian doctrine*).

Catholic elementary school students were taught about things divine and how to define *perfection*, *unity*, *nature*, and *substance*; they were taught about the church and how to define its attributes of *authority*, *infallibility*, and *indefectibility*, and how to describe the various ranks of the officers of the church, those in *minor orders* and *major orders*, and the prelates who ruled the church, from *monsignor* through the *Pope* (who could teach *ex cathedra*) and his *vicars apostolic* and *cardinals*. They were taught a taxonomy of sins: *original* and *actual*, *mortal* and *venial*, and *capital* and *material*, and about *predominant sin* or *ruling passion*, which might determine for each what constituted a *near occasion of sin*. But *grace* was available – *actual grace* and *sanctifying grace* – which came through the *sacraments* (the *sacraments of the living* and *sacraments of the dead*), with their *outward sign*, *matter*, and *form*, and the requisite *right intention* and *right dispositions*. Students learned that *confession* and *general confession* (not recommended for those with *scruples*), with its *absolution* and *penance*, could *remit the two punishments due to actual sins*, the *eternal punishment*, but only part of the *temporal punishment* in *purgatory*. For help with the latter, one sought a *plenary indulgence* or a *partial indulgence*. Catholics knew the *end of man*, that after death there would be a *particular judgment* that would send him to *hell*, *purgatory*, or *heaven*, but that there was to be a *general resurrection* followed by a *general judgment*, after which the souls of the just would live on in a *glorified body*, with its qualities of *brilliancy*, *agility*, *subtility*, and *impassibility*.

For some practices, Catholics had expressions ranging from the top to the bottom of Catholic idiom (see Wills (1972: 40), on the hypercorrect usage of the Catholic intelligentsia of the 1950s), e.g., from the formal 'receive the Eucharist' or 'receive Holy Communion' to the informal 'go to Communion,' to the antiformal 'hit the rail' (the communion, or altar, rail that separated the sanctuary from the nave of the church). The intelligentsia employed a reserved code of compressed, implicit expressions, such as when they advised one another to 'offer it up' (gladly to offer personal discomfort or frustration in place of the pains of the *church suffering* in *purgatory*) or excused themselves to 'make a visit' (to the Blessed Sacrament *reserved* in church). Even Catholic profanity was distinctive, an apt topic for a study such as that of Beccaria (2001).

Catholic communities were distinguished also by onomastics. Religion restricted the choice of personal names given in the sacraments of baptism and confirmation to 'saints' names' broadly understood, and affected even the toponymy of areas where Catholics lived. Spanish-speaking Catholics had left the mark of their religion on the toponymy of the western states in names that are still intact or that have been abbreviated, e.g., in the United States, Ventura (California), from *San Bonaventura*, and the Animas River (northern Colorado), from *Rio de las Animas Perdidas*. Later waves of Catholic immigrants used parish boundaries to create their own toponymy for the great cities in which they settled. Thus, when asked where they or another lived, they would reply with the name of the parish. This could have ethnic significance, e.g., St. Laurence O'Toole (Irish), St. Liborius (German), or St. John Nepomuk (Czech), or might simply indicate in which Catholic community they lived, with all of the socioeconomic and cultural implications of any other community designation. This toponymy was confusing to non-Catholics or even to Catholics from out of town, and confusion was compounded when the term 'parish' was dropped from the complete or abbreviated parish name, as when one would say that he was from 'Blessed Sacrament' or 'Holy Rosary' or from 'Sorrows' (Our Lady of Sorrows parish) or 'Immaculate' (Immaculate Conception parish).

Roman Catholic culture has undergone fundamental changes since the Second Vatican Council, and the American Catholic idiom described here is now obsolescent. Some of its features endure, but many have been displaced by new formulations, and, in the interests of interfaith relations, gender equity, etc., many peculiar usages have been eliminated altogether. It would be, perhaps, inexact to apply the term 'language death' to this case, but the fact remains that cultural changes are bringing about the extinction of a form of peculiarly Catholic mode of communication.

Christianity, Protestant

H Hillerbrand, Duke University, Durham, NC, USA

© 2006 Elsevier Ltd. All rights reserved.

Protestantism is one of the three major Christian traditions, alongside Roman Catholicism and Greek and Russian Orthodoxy. Its number of adherents worldwide is calculated to be 342 000 000 Core Protestants, to which should be added another 491 000 000 Wider Protestants, members of so-called independent traditions, which are referred to as Protestant by others. Statistics of adherents of religions are not always fully reliable, however, since they are often based on self-reported figures by the churches themselves. European countries with vestiges of the historical state-church system count baptized members (for example, in both Sweden and Finland approximately 82% of the respective populations), many of whom have no meaningful relationship to Christianity or Protestantism. Nonetheless, Protestants comprise about 44% of the adherents of world Christianity. Much like Roman Catholicism, Protestantism is not confined to Europe and North America but has increasingly been, since the 18th century, a global phenomenon. The importance of Protestantism can be seen in the fact that worldwide the overwhelming number of Christian publications come from Protestant sources and that a Christian 'megacensus,' which measures everything empirically measurable about Christianity, has found that 75% stem from Protestant initiatives.

Unlike Roman Catholic and Orthodox Christianity, however, Protestant Christianity is divided not only geographically and culturally, but also theologically and ecclesiastically. There is no single Protestant Church as such, as there is – despite various diversities – a single Roman Catholic Church. Quite the contrary, there are dozens upon dozens of Protestant Churches. Some of these, such as the Anglican Communion, are worldwide in scope and distribution of membership; others such as the Church of the Prussian Union are confined to a single country or area; still others such as the independent snake-handling congregations of Appalachia in the United States, are solitary congregations. Despite such diversity, which Catholics in the past used to buttress their own truth claims (since truth – as Bishop Bossuet noted in the 17th century – must be one, not many), virtually all of these traditions had their origin in staking out the same absolutist truth claims as have the Roman Catholic and Orthodox churches. Until the modern era, all Protestant churches insisted on their exclusive possession of Christian truth and, each in its own way, echoed the ancient notion, *extra ecclesiam nulla salus* – outside the church there is no salvation – except that Protestants had a way of defining 'church' rather subjectively.

The term 'Protestant' itself comes from the 'protest' which the German territorial rulers, supportive of Luther's movement of reform, lodged at the diet (parliament) at Speyer in 1529 against the decision of the Catholic rulers to carry out the stipulations of the Edict of Worms against Martin Luther. Thus, one may define Protestant as all those individuals and churches that affirm the Bible as the sole norm of truth and, in so doing, protest the authority of the Roman pontiff and the Catholic Church. The term itself is, therefore, a negative one, even though some interpreters of the 1529 action have pointed to the root meaning of the Latin *protestari* as denoting 'to bear witness' as is still found in the word 'protestation,' meaning strong declaration or affirmation. Protestantism may thus be defined with a number of positive assertions, as one also.

Christianity, Protestant

H Hillerbrand, Duke University, Durham, NC, USA

© 2006 Elsevier Ltd. All rights reserved.

Protestantism is one of the three major Christian traditions, alongside Roman Catholicism and Greek and Russian Orthodoxy. Its number of adherents worldwide is calculated to be 342 000 000 Core Protestants, to which should be added another 491 000 000 Wider Protestants, members of so-called independent traditions, which are referred to as Protestant by others. Statistics of adherents of religions are not always fully reliable, however, since they are often based on self-reported figures by the churches themselves. European countries with vestiges of the historical state-church system count baptized members (for example, in both Sweden and Finland approximately 82% of the respective populations), many of whom have no meaningful relationship to Christianity or Protestantism. Nonetheless, Protestants comprise about 44% of the adherents of world Christianity. Much like Roman Catholicism, Protestantism is not confined to Europe and North America but has increasingly been, since the 18th century, a global phenomenon. The importance of Protestantism can be seen in the fact that worldwide the overwhelming number of Christian publications come from Protestant sources and that a Christian 'megacensus,' which measures everything empirically measurable about Christianity, has found that 75% stem from Protestant initiatives.

Unlike Roman Catholic and Orthodox Christianity, however, Protestant Christianity is divided not only geographically and culturally, but also theologically and ecclesiastically. There is no single Protestant Church as such, as there is – despite various diversities – a single Roman Catholic Church. Quite the contrary, there are dozens upon dozens of Protestant Churches. Some of these, such as the Anglican Communion, are worldwide in scope and distribution of membership; others such as the Church of the Prussian Union are confined to a single country or area; still others such as the independent snake-handling congregations of Appalachia in the United States, are solitary congregations. Despite such diversity, which Catholics in the past used to buttress their own truth claims (since truth – as Bishop Bossuet noted in the 17th century – must be one, not many), virtually all of these traditions had their origin in staking out the same absolutist truth claims as have the Roman Catholic and Orthodox churches. Until the modern era, all Protestant churches insisted on their exclusive possession of Christian truth and, each in its own way, echoed the ancient notion, *extra ecclesiam nulla salus* – outside the church there is no salvation – except that Protestants had a way of defining 'church' rather subjectively.

The term 'Protestant' itself comes from the 'protest' which the German territorial rulers, supportive of Luther's movement of reform, lodged at the diet (parliament) at Speyer in 1529 against the decision of the Catholic rulers to carry out the stipulations of the Edict of Worms against Martin Luther. Thus, one may define Protestant as all those individuals and churches that affirm the Bible as the sole norm of truth and, in so doing, protest the authority of the Roman pontiff and the Catholic Church. The term itself is, therefore, a negative one, even though some interpreters of the 1529 action have pointed to the root meaning of the Latin *protestari* as denoting 'to bear witness' as is still found in the word 'protestation,' meaning strong declaration or affirmation. Protestantism may thus be defined with a number of positive assertions, as one also.

Historically, Protestantism had its beginnings early in the 16th century in the various efforts to engage the Roman Catholic Church in reform of practice and theology. These efforts were spearheaded by Martin Luther, professor at the University of Wittenberg in Central Germany, and his 95 Theses against the practice of indulgences. The prompt verdict of excommunication against Luther and his supporters issued in 1521 meant a parting of the ways and, before long, the establishment of new churches separate from the Roman Church.

It is a truism that, once the break had occurred, subsequent theological reflection convinced the Protestant reformers that their understanding of text and message differed categorically from that of the old church. There surely should be no doubt – the exceptions seem to be systematic theologians who tend to view the past from the perspective of the present – that from a certain time onward in the Reformation controversy, the reformers and their successors would not have returned to the Catholic Church even if they had been welcomed with open arms.

Soon it became obvious, however, that common opposition against the Roman church and its theology did not mean common belief. Dissension arose within the movement of reform, first among those who wished for a more selective church and repudiated the baptism of infants, later called Anabaptists, then among those who held different interpretations of the meaning of the Lord's Supper. Indeed, this particular issue became the cause for a far-reaching split among the ranks of the reformers, with the line drawn most sharply between the Lutheran and the Calvinist traditions, the latter tracing its origin to John Calvin, a Frenchman whose reforming activities centered in Geneva, Switzerland. Calvin understood the bread and wine of the Communion service to signify the spiritual union between the believer and Christ, while Luther held that these elements were his true body and blood.

Calvin's tradition has had a particularly strong importance in the Anglo-Saxon world, while Lutheranism tended to be found in central and northern Europe. In the England of King Henry VIII, religious agitation together with the strong will of the king led to the establishment of a new church that initially focused on the repudiation of papal authority but subsequently, under Edward VI and Elizabeth I, took on a more Protestant ring. Even as on the Continent earlier in the century, there had been those for whom the reforms undertaken did not go far enough, so there were those in England during Elizabeth's reign who called for reform that was more extensive and a purer church. Dubbed Puritans by their opponents, these ardent reformers owed a great debt to Calvin, and became a lasting element in English Protestantism. Mainstream Protestantism in England, soon dubbed Anglican, saw its distinctive feature in the affirmation of a *via media* between Catholicism and Protestantism.

The story of Protestantism in England gained in excitement in the course of the 17th century with the turbulence of the civil war and its mixture of political and religious concerns. This brought the emergence of several dissenting churches that, while small in numbers, have lastingly influenced English Protestantism to this day: Baptists, Quakers, and Congregationalists. Similar discontent with mainstream Protestantism in England in the 18th century led to the emergence of the Wesleyan movement, named after the Oxford don and Church of England clergyman John Wesley. Eventually, this movement separated from the Church of England and subsequently became known as Methodist.

Continental Protestantism was characterized in the 17th century by an emphasis on proper doctrine (thus, the label Orthodoxy), which later gave it the unmerited reputation of having little empathy for the praxis of Christianity. Orthodox theology focused on delineating the distinctive doctrines of the respective traditions, which led, among other affirmations, to the delineation of the notion of the verbal inspiration of the Bible. Late in the century, Philipp Jakob Spener, a German Lutheran clergyman, influenced by such English devotional writers as William Perkins and William Ames, offered a proposal for renewing the church in a book entitled *Pious Desires*. This book triggered the movement of Pietism, which can be seen as a Continental parallel to the Wesleyan movement in England.

Of equal, if not greater, importance for the course of Protestantism were the intellectual changes emanating from the European Enlightenment in the late 17th and 18th centuries. The searching reexamination of long-held scholarly, philosophical, and religious views led to an increasing attack on the conventional understanding of the Bible as well as on traditional theology. A group of English thinkers labeled Christian Deists challenged the time-honored understanding of the Bible as a revealed book, repudiating not only the concept of revelation but miracles and prophecy as well. Protestantism became divided into two camps: those that affirmed traditional Christian doctrines and those who reinterpreted these doctrines.

In the 19th and even the 20th century, the history of Protestantism was less the story of great church leaders or institutions than it was the story of theologians, such as Friedrich Schleiermacher, Albrecht Ritschl, David Friedrich Strauss, or Adolf Harnack. These theologians undertook to reinterpret the

Christian faith in the face of the challenges of modernity. Others, often less in the public eye, affirmed traditional notions. Twentieth century Protestantism was marked by several theological waves. Some, such as Neo-Orthodoxy, were theologically conservative, while others, such as Liberation Theology, tended to be more liberal. The great theme of 20th century Protestantism, however, was its globalization and its eroding numbers and importance in Europe.

Protestantism was successfully transplanted from old to New England in the 17th century. Many immigrants who came to North America were religious dissenters, such as the Mennonites, the Amish, the Independents, or the Baptists, for whom the new continent was the biblical city on a hill, where they could practice their faith unhindered by government, though they often manifested the same kind of intolerance that they themselves had experienced in their European homelands.

Theologically, several affirmations characterize Protestantism, of which the centrality of the Bible as sole authority for life and faith holds the primacy of place and importance. The Latin phrase *sola scriptura* ('Scripture alone') expresses this centrality, which implies the rejection of the church and its traditions as normative authority as is variously the case in Roman Catholicism and Greek and Russian Orthodoxy. Since it is the presupposition of this Protestant premise that the meaning of the Bible is clear and self-evident, Protestantism has no teaching office (*magisterium*) as does the Roman Catholic Church. Thus, the distinctive Protestant hallmark has to do with authority.

A second Protestant assertion relates to the doctrine of justification, which explains how humans are reconciled with God. Catholic teaching has held in varying ways that such justification entails a process of divine and human cooperation, where humans will marshal their moral prowess to which divine grace is added. This Catholic notion of cooperation, often mislabeled as work righteousness by Protestants, was countered in Protestant theology with the insistence that justification is solely attributable to divine grace, which humans appropriate solely by faith. Here, too, Protestant nomenclature invoked the Latin *sola* (alone) to insist that justification is *sola gratia, sola fide*, solely by grace, solely by faith.

Beyond these basic affirmations, Protestantism is marked by theological diversity. Protestant diversity finds its explanation in the absence of a central authoritative entity – either person or structure – in Protestantism that would exercise normative authority (and power). The Protestant recourse to the Bible, or the Word of God as the ultimate authority, produced multiple divergent interpretations, and new theological or biblical interpretations frequently assumed structural concreteness. Yet it seems neither fair nor theologically accurate to contrast the relatively homogeneous Catholic and Orthodox churches with the diversity of Protestant denominations – and to find in this diversity proof positive for the nonviability of Protestant truth claims. The Roman Catholic Church sustains its theological homogeneity through excommunication or the voluntary separation of dissenting members, indicating that it is not itself able to maintain unity of interpretation. The very existence of Orthodox and Protestant traditions suggests that the Roman Catholic Church has not been able to sustain its truth claims universally but has sloughed off dissent within its ranks. In Protestant churches, excommunication and dissent have likewise led to separation, but with a difference: the establishment of new groupings and churches. The phenomenon of new ecclesial structures has been particularly prominent in places where the legal freedom to do so existed. The absence of established churches in North America and the non-European world has allowed dissent from the mainstream to express itself organizationally and sociologically in the form of new churches, each of which claims its own truth.

The diversity of Protestant churches, especially pronounced in the United States, entails two consequences. One is the difficulty of speaking of **the** Protestant understanding of almost any topic, be it worship, doctrine, ethics, etc. Even as regards the traditional hallmark of Protestantism, the priority of grace in salvation, there are diverse Protestant notions as to exactly how divine grace and human effort are to be related. Second, there is also the increasingly popular (at least among scholars) tendency to use the plural and speak of Protestantisms to denote the empirical reality of Protestant diversity. This view, which simultaneously speaks of Catholicisms or Christianities, ignores the fundamental unity in diversity by favoring the latter rather than the former.

The closing decades of the 20th century saw a striking vitality of theologically conservative Protestant churches, especially in places such as Korea, Central America, and Africa. Pentecostal churches have seen dramatic increases in membership. This is in contrast to stable membership numbers and a more liberal theological outlook in the European and North American Protestant churches. The important question, as regards the future of Protestantism, will be if these recent developments must be seen as harbingers of identity and place of Protestantism in the 21st century.

Christmas Island: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

An Australian Territory since 1958, Christmas Island is a small tropical isle in the eastern sector of the Indian Ocean, 2600 km northwest of Perth, Western Australia. Its closest neighbor is Java, 360 km away. The uninhabited island was discovered and named on Christmas Day of the year 1643 by Captain William Mynors of the East India Ship Company, but it was not until 1888 that Christmas Island was annexed by Britain and settled. The Clunies-Ross brothers from neighboring Cocos-Keeling Islands (some 900 km to the southwest) established a settlement at Flying Fish Cove to collect timber and supplies for the growing industry on Cocos, and when phosphate mining began in the 1890s, Christmas Island became increasingly populated. The earliest settlers spoke English and Cocos Malay, a unique version of Malay that has been isolated from the mainstream language for over 150 years. Early arrivals from China mainly spoke Cantonese. In fact, many early place names on Christmas Island are Cantonese words, such as *Poon Saan*, which means 'halfway up the hill'. Postwar arrivals who came from Penang introduced other Chinese languages including Hakka, Hainese, Hokkien, and Teochew, while those from Singapore introduced Mandarin. Malay is widely spoken by the Malay Community present on the island and, even though English is the official language of Christmas Island, there are many residents who generally communicate in Malay or one of the four Chinese dialects. Because English was not a prerequisite for employment, a sizable proportion of today's community is not fluent in English and many residents still converse in their native tongue. The Australian Bureau of Statistic Census of 2001 recorded a total population of 1508 people on Christmas Island, with an ethnic composition of approximately 60% Chinese, 10–15% European, and 25–30% Malay. The influx of tourists has also had an impact on the island's language. Indonesian is frequently spoken along with many of the Chinese languages. Thai, Japanese, German, and a few other European languages are sometimes also heard.

Chrysippos (ca. 282–208 B.C.)

P Swiggers and A Wouters, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Born in Soli (Cilicia), Chrysippus went to study in Athens, where he received his philosophical training in the Platonist academy with Arcesilaus and subsequently in the Stoic school led by Cleanthes of Assos. He succeeded his master, Cleanthes, and became the third head of the Stoic school. He died in Athens around 205 B.C.

Chrysippus was an extremely influential thinker and highly prolific writer, but unfortunately very little is left of the approximately 700 titles attributed to him by Diogenes Laertius, whose *Lives of the philosophers* remains our main source of information on Chrysippus and other Stoic philosophers. Chrysippus's main fields of research were dialectics and language study (i.e., philosophy of language and grammar), and he seems to have laid the foundations of Stoic linguistic thought. For Chrysippus, the term *dialektikê* ('dialectics') referred to the study of signs and 'things signified.' From the catalogue of his lost writings it is possible to get an idea of the extent and technicality of his philosophical-linguistic work (more than 100 titles). The areas of dialectics and language study investigated by Chrysippus covered the following topics: (a) judgments and other types of sentences (disjunctive judgments, hypothetical judgments, consequents; questions, queries, answers, orders); (b) predicates and classes (species, genera, contrary terms, and relative terms); (c) words, word classes, and their morphological and syntactic behavior (this domain includes writings on cases, on proper names, on the elements of speech, on the arrangement of expressions); and (d) the origin of words (etymology). The first three kinds of topics fall within Stoic logic and theory of meaning: the composition, the nature, the content, and the function of sentences

Chrysippos (ca. 282–208 B.C.)

P Swiggers and A Wouters, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Born in Soli (Cilicia), Chrysippus went to study in Athens, where he received his philosophical training in the Platonist academy with Arcesilaus and subsequently in the Stoic school led by Cleanthes of Assos. He succeeded his master, Cleanthes, and became the third head of the Stoic school. He died in Athens around 205 B.C.

Chrysippus was an extremely influential thinker and highly prolific writer, but unfortunately very little is left of the approximately 700 titles attributed to him by Diogenes Laertius, whose *Lives of the philosophers* remains our main source of information on Chrysippus and other Stoic philosophers. Chrysippus's main fields of research were dialectics and language study (i.e., philosophy of language and grammar), and he seems to have laid the foundations of Stoic linguistic thought. For Chrysippus, the term *dialektikê* ('dialectics') referred to the study of signs and 'things signified.' From the catalogue of his lost writings it is possible to get an idea of the extent and technicality of his philosophical-linguistic work (more than 100 titles). The areas of dialectics and language study investigated by Chrysippus covered the following topics: (a) judgments and other types of sentences (disjunctive judgments, hypothetical judgments, consequents; questions, queries, answers, orders); (b) predicates and classes (species, genera, contrary terms, and relative terms); (c) words, word classes, and their morphological and syntactic behavior (this domain includes writings on cases, on proper names, on the elements of speech, on the arrangement of expressions); and (d) the origin of words (etymology). The first three kinds of topics fall within Stoic logic and theory of meaning: the composition, the nature, the content, and the function of sentences

(and their constituents, such as subject terms, predicates) were the essential prerequisite for a correct analysis of syllogisms, ambiguities, fallacies, *aporiai,* and other philosophical puzzles. Chrysippus played a major role in showing the importance of linguistic-grammatical study (focusing on the structure of the proposition, on propositional content, and on the meaning of its constituent parts) for logical analysis and for a correct understanding of statements (as referring to states of affairs).

Chukotko-Kamchatkan Languages

G D S Anderson, Max Planck Institute, Leipzig, Germany, and University of Oregon, Eugene, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Chukotko-Kamchatkan

Chukotko-Kamchatkan, formerly also known as Luor[a]vetlan, is a small family of languages spoken in extreme northeastern Siberia on the Chukotka Peninsula, opposite Alaska and the large Kamchatka Peninsula in far Eastern Siberia. The family consists of four remaining languages, Alutor, Chukchi, Itelmen, and Koryak. All of the languages in the group, excluding Chukchi, are endangered; Kerek became extinct in the 1990s.

Alutor (*Ethnologue* code ALR), also known as Alyutor or Palana Koryak, is spoken by some 200 people in the villages of Vyvenka and Rekinniki in the Koryak National District, in the northeast Kamchatka Peninsula. Chukchi (*Ethnologue* code CKT) is spoken by some 10 000 people, primarily on the Chukchi Peninsula of northeastern Siberia. In English language literature, especially older works, the language is sometimes spelled Chukchee as well. Several local variants exist, but differences are relatively minor. More celebrated were the once active phonological differences in men's and women's speech, seen in the following word pair: (men) *reqərkən* = (women) *tzeqətzən* 'what is s/he making/doing?' (Kämpfe and Volodin, 1995: 8). Itelmen (*Ethnologue* code ITL) is also known as Kamchadal. Itelmen is currently moribund, with fewer than 100 speakers. Itelmen speakers are found primarily in the Tigil region, in Kovran, and in the Upper Khairiuzovo villages on the Kamchatka Peninsula. There were originally at least three Itelmen languages, two gradually giving way to Russian over the past two centuries, and they are now extinct. Only the Western dialect remains; it is sometimes divided into separate Kovran and Sedanka varieties. Kerek (*Ethnologue* code KRK) became extinct in the late 1990s. It was closely related to Koryak (*Ethnologue* code KPY); Koryak has some 3500 speakers scattered across the Koryak National Okrug, on the northern half of Kamchatka. An alternate name is Nymylan. There are several divergent varieties, some now considered separate languages (Alutor). Dialects include Chavchuven, Apukin, and Kamen.

Itelmen stands in isolation from the northern languages genetically, with the speech representing a southern branch. It is sometimes debated whether Itelmen is related at all to Northern Chukotko-Kamchatan, and it is indeed different in numerous ways, but these are attributable rather to different substrate populations and various locally defined internal developments within Northern and Southern Chukotko-Kamchatkan, and their ultimate genetic unity seems clear. The northern branch in many

(and their constituents, such as subject terms, predicates) were the essential prerequisite for a correct analysis of syllogisms, ambiguities, fallacies, *aporiai,* and other philosophical puzzles. Chrysippus played a major role in showing the importance of linguistic-grammatical study (focusing on the structure of the proposition, on propositional content, and on the meaning of its constituent parts) for logical analysis and for a correct understanding of statements (as referring to states of affairs).

Chukotko-Kamchatkan

Chukotko-Kamchatkan, formerly also known as Luor[a]vetlan, is a small family of languages spoken in extreme northeastern Siberia on the Chukotka Peninsula, opposite Alaska and the large Kamchatka Peninsula in far Eastern Siberia. The family consists of four remaining languages, Alutor, Chukchi, Itelmen, and Koryak. All of the languages in the group, excluding Chukchi, are endangered; Kerek became extinct in the 1990s.

Alutor (*Ethnologue* code ALR), also known as Alyutor or Palana Koryak, is spoken by some 200 people in the villages of Vyvenka and Rekinniki in the Koryak National District, in the northeast Kamchatka Peninsula. Chukchi (*Ethnologue* code CKT) is spoken by some 10 000 people, primarily on the Chukchi Peninsula of northeastern Siberia. In English language literature, especially older works, the language is sometimes spelled Chukchee as well. Several local variants exist, but differences are relatively minor. More celebrated were the once active phonological differences in men's and women's speech, seen in the following word pair: (men) *reqərkən* = (women) *tzeqətzən* 'what is s/he making/doing?' (Kämpfe and Volodin, 1995: 8). Itelmen (*Ethnologue* code ITL) is also known as Kamchadal. Itelmen is currently moribund, with fewer than 100 speakers. Itelmen speakers are found primarily in the Tigil region, in Kovran, and in the Upper Khairiuzovo villages on the Kamchatka Peninsula. There were originally at least three Itelmen languages, two gradually giving way to Russian over the past two centuries, and they are now extinct. Only the Western dialect remains; it is sometimes divided into separate Kovran and Sedanka varieties. Kerek (*Ethnologue* code KRK) became extinct in the late 1990s. It was closely related to Koryak (*Ethnologue* code KPY); Koryak has some 3500 speakers scattered across the Koryak National Okrug, on the northern half of Kamchatka. An alternate name is Nymylan. There are several divergent varieties, some now considered separate languages (Alutor). Dialects include Chavchuven, Apukin, and Kamen.

Itelmen stands in isolation from the northern languages genetically, with the speech representing a southern branch. It is sometimes debated whether Itelmen is related at all to Northern Chukotko-Kamchatan, and it is indeed different in numerous ways, but these are attributable rather to different substrate populations and various locally defined internal developments within Northern and Southern Chukotko-Kamchatkan, and their ultimate genetic unity seems clear. The northern branch in many

interpretations has further subgroups of Alutor and Koryak (and Kerek), in opposition to Chukchi.

Along the coasts, Chukchi people live as sea mammal hunters, like the local Yup'ik populations, but they live as reindeer herders in the interior. Approximately three-quarters of the Chukchi live as reindeer herders. Northern Kamchatkan groups mainly practice reindeer-oriented economies and fishing and sea mammal hunting along the coasts. The Itelmen live primarily as subsistence fishers.

Chukotko-Kamchantkan languages in general, but the northern ones in particular, are characterized by a range of features that set them apart from many indigenous Siberian languages, but also reflect a number of areally common features. First, many words in Chukotko-Kamchatkan languages are very long (e.g., Chukchi *ga-npənačg-ərgəna-qora-ma* 'with the old men's reindeers' (Skorik, 1986: 107)), and initial *ŋ-* is common (as is typical of northern and eastern Siberian languages (Anderson, 2003). Clusters of stop + *ŋ* are also found. Example (1) is from Skorik (1986: 79, 85) (cf. Itelmen *ŋosx* 'tail' and *ŋeyŋe* 'mountain' (Volodin, 1976: 31)):

(1)	Chukchi	Koryak	Alutor	Kerek	gloss
	ŋoyŋən	ŋoyŋən	ŋoyŋən	ŋuyŋən	'tail'
	ŋəron-laŋ-o	ŋəyon-laŋ	ŋərun-laŋ	nəyuq-laŋu	'3 together'

Compare Kerek *tŋivek* 'to send' (Skorik, 1986: 89) with Itelmen *pŋilpnəl* 'root' (Skorik, 1986: 78)). Itelmen shows an unusual tolerance to consonant clusters word-initially, as well as ejective consonants that the northern languages do not share. Thus, words such as *klfknan* 'it fell out' and *kstk'ɬknan* 'he jumped' may be found in Itelmen.

Northern Chukotko-Kamchatkan languages stand out for their areally atypical system of vowel harmony. Vowels belong to one of two harmonic classes, strong/dominant and weak/recessive. A strong vowel triggers strong allophones throughout the word, and therefore a vowel in an affix may trigger alternation in stem vowels, as shown in Example (2) for Koryak:

(2)	weyem	'river' >	wayam**əŋ**	'river-DAT'
	mil'ut	'hare' >	mel'ot**aŋ**	'hare-DAT'
	eñpič	'father' >	añpeče-na-**naŋ**	'father-AUGM-DAT'

Note: ***geyqə-miml-e*** 'with water' vs. ***gawən-memlə-ma*** 'with water' (Zhukova, 1972: 111–112; 120).

Among the most characteristic features of Chukotko-Kamchatkan morphology is the frequent use of circumfixes (combined prefix + suffix combinations) to encode a variety of inflectional categories, both nominal and verbal, some of which appear to be very old in the family. In Koryak, this is realized as ***ga-čol'-ma*** 'with salt' (Zhukova, 1972: 120), and in Chukchi it is ***ga-npənačg-ərgəna-qora-ma*** ' with the old men's reindeers' (Skorik, 1986: 107). In Koryak, *y(A)-. . .-ŋ* (Zhukova, 1972: 202):

(3)	**y**-ačačgañ-**ŋ**-ək	**ye**-lqəñ-**ŋ**-ək
	DESID-laugh-DESID-INF	DESID-leave-DESID-INF
	'want to laugh'	'want to leave'

In Chukchi, *re-. . .-ŋ* (Kämpfe and Volodin, 1995: 88):

(4)	vinretə-rkən	>	**re**-vinretə-**ŋə**-rkən
	help-IMPERF. REALIS		DESID-help-DESID-IMPERF.REALIS
	'he helps'		'he wants to help'

Among the wider relationships that have been proposed for Chukotko-Kamchatkan languages, none widely accepted by specialists, are connections with Uralic, Eskimo-Aleut, and 'Eurasian,' among others.

Church Slavonic

C M MacRobert, Oxford University, Oxford, UK

Church Slavonic is a generic term for the closely related, highly conservative varieties of Slavic language used for liturgical purposes by the Eastern Orthodox Slavs (Belorussian, Bulgarian, Macedonian, Russian, Serbian, Ukrainian) and the Ukrainian Uniates, and also by the Romanians until the 16th century and, until the introduction of services in the vernacular, the Roman Catholic Croats of the Slavonic rite. In the medieval period, Church Slavonic also had the wider functions of a literary language among most of these peoples.

Church Slavonic originated in the translations of Scripture and liturgy made mainly from Greek by SS Cyril and Methodius and their associates in the late 9th and early 10th centuries (*see* **Old Church Slavonic**). The basic vocabulary, grammatical forms, and pronunciation of these texts predominantly followed the usage of Slavs in the southeast Balkans, while syntax and word-formation were to a large extent modeled on Greek.

Two developments signal the transition, by the end of the 11th century, from Old Church Slavonic to Church Slavonic. One was the emergence of local varieties, such as Croatian, Russian, and Serbian Church Slavonic, which compromised between traditional pronunciation and grammatical forms and the vernacular usage of the area. Initially unsystematic, these modified varieties rapidly stabilized to local norms that in the hands of competent scribes attained a high degree of regularity. The other development consisted in revisions of syntax and vocabulary, which seem to have been motivated partly by the

Church Slavonic

C M MacRobert, Oxford University, Oxford, UK

© 2006 Elsevier Ltd. All rights reserved.

Church Slavonic is a generic term for the closely related, highly conservative varieties of Slavic language used for liturgical purposes by the Eastern Orthodox Slavs (Belorussian, Bulgarian, Macedonian, Russian, Serbian, Ukrainian) and the Ukrainian Uniates, and also by the Romanians until the 16th century and, until the introduction of services in the vernacular, the Roman Catholic Croats of the Slavonic rite. In the medieval period, Church Slavonic also had the wider functions of a literary language among most of these peoples.

Church Slavonic originated in the translations of Scripture and liturgy made mainly from Greek by SS Cyril and Methodius and their associates in the late 9th and early 10th centuries (*see* **Old Church Slavonic**). The basic vocabulary, grammatical forms, and pronunciation of these texts predominantly followed the usage of Slavs in the southeast Balkans, while syntax and word-formation were to a large extent modeled on Greek.

Two developments signal the transition, by the end of the 11th century, from Old Church Slavonic to Church Slavonic. One was the emergence of local varieties, such as Croatian, Russian, and Serbian Church Slavonic, which compromised between traditional pronunciation and grammatical forms and the vernacular usage of the area. Initially unsystematic, these modified varieties rapidly stabilized to local norms that in the hands of competent scribes attained a high degree of regularity. The other development consisted in revisions of syntax and vocabulary, which seem to have been motivated partly by the

desire to eliminate outdated or unfamiliar linguistic material, but also aimed to make texts conform to a received Greek version and to produce more closely literal translations. The earliest systematic revisions are associated with Preslav, the capital of Bulgaria in the 10th century, when a number of early Church Slavonic revisions, new translations, and original compositions came into existence. There also appears to have been a revision of Croatian Church Slavonic texts on the basis of Latin sources in the 12th century.

Revisionist tendencies culminated by the 14th century in comprehensive reform of scriptural and liturgical translations into Bulgarian and Serbian Church Slavonic. This development has been associated with the Bulgarian patriarch Euthymius (elected patriarch in 1375; exiled by the Turks in 1393), though more recent research suggests it began in the early part of the century, perhaps on Mount Athos. The resulting standardized orthography, conservatism in grammatical forms and vocabulary, and highly literalistic translational practice were introduced among the East Slavs from the end of the 14th century, albeit with some adjustments to pre-existing local usage. The late 16th and early 17th centuries saw attempts in the Ukraine at systematic description of this late and composite type of Church Slavonic, on the model of Greek and Latin grammars; the most comprehensive of these, compiled by Meletij Smotryc'kyj in the early 17th century and subsequently modified to conform to Muscovite practice, remained the fullest description of Russian Church Slavonic until the 19th century.

Further revisions of Church Slavonic texts initiated in Muscovy or the Ukraine in the 16th and 17th centuries, though controversial in their time, dealt with minor textual discrepancies or the detail of grammatical and orthographical norms. A final standardization was effected in the publications approved by the Synod of the Russian Orthodox Church in the 18th century. Thanks to the dissemination of these printed books in the Balkans, the Orthodox Bulgarians, Macedonians, and Serbs came to use 'Synodal' Russian Church Slavonic, albeit with their own pronunciations.

Modern Church Slavonic does not stand in a simple genetic relationship to other Slavic languages. Its texts may be understood in different ways and to varying degrees by Slavs of differing linguistic background and, as a result of literalistic translational practices aiming at morpheme for morpheme equivalence, some of them are intelligible only with the help of their Greek originals. It is virtually a closed system, for though new texts can be created if need arises, they are acceptable as Church Slavonic only insofar as they reproduce traditional constructions and phraseology. While its liturgical use still prevails in the Russian Orthodox Church, among the Orthodox South Slavs, Church Slavonic tends increasingly to be supplanted by modern vernacular translations, and survives mainly as a vehicle for the traditional corpus of hymns.

Chuvash

L Johanson, Mainz University, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Location and Speakers

Chuvash (*čăvaš čĕlxi, čăvašla*) is the only modern representative of the Oghur (or Bulgar) branch of the Turkic language family. It is spoken in the Volga-Ural region, partly in the Chuvash Republic (*Čăvaš Respubliki*) at the 'Great Bend' of the Volga River. The Chuvash Republic (the capital is Cheboksary, *Šupaškar*) was established in 1990 within the Russian Federation; its forerunner was the Chuvash Autonomous Soviet Socialist Republic, created in 1925. The Chuvash have majority status in the Republic, forming nearly 70% of the population. Over three-fourths of the population regard Chuvash as their native language.

More than half of the speakers of Chuvash live outside the Republic, especially in the south and southwest parts of Tatarstan, in the central and west parts of the Bashkortostan, and in the Kuybyshev, Ulyanovsk, and Samar provinces. Speakers of Chuvash also live in other parts of Russia, in West and East Siberia, in the Far East, and in some Central Asian republics. The total number of Chuvash-speaking people is nearly 2 million. According to a law adopted in 1991, Chuvash and Russian are the official languages of the Republic. Russian is the medium of communication between nationalities and the main language of instruction. However, the efforts to maintain Chuvash are strong, even in the younger generation.

Origin and History

Parts of the old Oghur tribal confederation, originally based in the Baikal Lake region, moved west and arrived, in the mid-5th century, in the European steppe, where they established states on the Kuban, Danube, and Volga rivers. They mostly assimilated linguistically, a well-known example being the Slavicization of Bulgar groups in the Balkans. At the end of the 9th century or earlier, Oghur groups settled in the Volga-Kama region, where they established the Volga Bulgar kingdom, with its center on the middle and lower course of the Volga River. They accepted Islam as early as 922. After the destruction of this state by the Mongols in the 13th century, the Volga Bulgars and other groups of the region became subject to the Golden Horde.

Early Oghur is unknown except for the evidence found in some proper names and old loanwords. Chuvash, which was recorded for the first time in the 18th century in word lists, texts, and one grammar, is considered closely related to Volga Bulgar and other old varieties of the Oghur type. Volga Bulgar is partly known from tombstone inscriptions found on the left bank of the Volga River, dating to the 13th and 14th centuries. Several linguistic features recorded in these epitaphs do not, however, fit very well with the known features of Chuvash. It is thus still not quite clear that Chuvash is a direct descendant of Volga Bulgar. It is also unknown whether the ancestors of the Chuvash took part in the written culture of the Bulgars. There are no Volga Bulgar epitaphs on the territory of the Chuvash Republic. The fact that Chuvash is one of the very few Turkic languages that is not strongly influenced by Islam may indicate that the ancestors of the Chuvash were not affected by the Volga Bulgar Islamic culture.

Related Languages and Language Contacts

Chuvash is the result of the oldest known split within the Turkic family. Its origins reside in the language of Oghur Turkic group. Chuvash has played a key role in comparative Turkic linguistics, especially in discussions about a possible genealogical relationship of Turkic, Mongolic, and Tungusic within an Altaic language family. According to an older view, Chuvash constitutes an independent Altaic language. The hypothesis of an Altaic protolanguage relies on reconstructions on the basis of words shared by Turkic, Mongolic, Tungusic, and sometimes other languages, such as Korean and Japanese. Deviant Chuvash consonant representations have been used to reconstruct a Proto-Altaic phonology.

Chuvash words with *r* and *l* sometimes correspond to Common Turkic words with *z* and *š* (e.g., Chuvash *čul* 'stone' vs. Common Turkic *ta:š*). This is an archaic Oghur feature. Two Samoyed words that can be traced back to **yür* 'hundred' and **kil'* 'winter' have obviously been copied from Oghur words containing the same final consonants. The corresponding Chuvash words are *śĕr* and *xĕl*, whereas other Turkic languages display forms ending in *-z* and *-š*, respectively (e.g., Turkish *yüz*, *kış*). Chuvash words with *r* and *l* sometimes have Mongolic equivalents with *r* and *l* (e.g., *čul* 'stone' vs. *čilaγun*). Cases such as these have been used to reconstruct the special Proto-Altaic elements r^2 and l^2, which are thought to be represented by *r* and *l* in Mongolic and Chuvash, whereas they have developed into *z* and *š* in Common Turkic. Scholars who do not accept the Altaic hypothesis

explain these and other correspondences by contact relationship. In this case, the assumption is that an Oghur language of the Chuvash type, with certain features, was the source of the oldest layer of Turkic loanwords in Mongolic. Tungusic, in turn, is thought to have borrowed words with these features from Mongolic.

Complex processes of linguistic assimilation have taken place in the Volga-Kama region since the 10th century. The Bulgar influence on East Finnic, Slavic, and early Kipchak Turkic was considerable. Ancestors of the Chuvash assimilated speakers of Udmurt (Votyak) and Meadow Mari (Cheremis). The assimilation of local populations led to strong substrate influences, especially from Mari. The term 'Chuvash,' first documented in Russian chronicles of the 16th century, originally referred to groups that also included speakers of Mari. On the other hand, the designation 'Cheremis' was also applied to Chuvash. After the Mongol conquest, from the 14th century on, Kipchak-speaking newcomers played an important role in the area. Speakers of Volga Bulgar were linguistically influenced by them. Parts of them assimilated Volga Bulgars and other Oghur-speaking groups, which led to substratum influence. What is known as Chuvash today remained relatively uninfluenced by the Kipchak wave. In its more recent linguistic history, however, Chuvash has been closely connected with Kipchak Turkic through massive Tatar impact.

The Written Language

Standard Chuvash is written with a Cyrillic-based alphabet that includes a few special letters. It goes back to a script system established by Ivan Jakovlev (1848–1930), which mirrors the pronunciation of the Anatri dialect. The alphabet was reformed in 1938 and has remained unchanged since then. It basically represents phonemes, and few allophones.

Distinctive Features

Chuvash shares basic linguistic features with other Turkic languages, preserving numerous so-called Common Turkic traits. It exhibits most linguistic features typical of the Turkic family (*see* **Turkic Languages**). It is, for example, an agglutinative language with suffixing morphology, sound harmony, and a head-final constituent order. On the other hand, it strongly deviates from Common Turkic in some respects, particularly in its phonology. In the following suffix notations, capital letters indicate phonetic variation (e.g., A = ă/ĕ). Hyphens are used to indicate morpheme boundaries.

Phonology

Chuvash phonology displays many irregular and complicated sound changes. This is especially true of the vowels, of which correspondences with Common Turkic vowels are far from unequivocal. For instance, the Common Turkic vowel *a* is represented by *u* in words such as *ut* 'horse' (cf. Tatar *at*), but by *ï* in words such as *pïr-* 'to go' (cf. Tatar *bar-*). Chuvash possesses the reduced vowels *ă* and *ĕ* (e.g., *tăr-* 'to stand', *pĕr* 'one'), which have their counterparts in neighboring languages, including Tatar, without corresponding to them in a systematic way. Originally long vowels are generally not preserved in Chuvash. In some cases, however, they are represented by diphthongs (e.g., *kĕvak* 'blue' < *kö:k*).

Chuvash has a rather reduced consonant inventory in comparison with most other Turkic languages. Under Slavic influence, palatalized and nonpalatalized consonants are distinguished, the palatalized ones occurring before and after front vowels. Chuvash *r* sometimes corresponds to an Old Turkic interdental *δ*, as in *ura* 'foot' vs. *aδaq*. This is not necessarily an archaic feature. In cases such as this, early Bulgar *δ* seems to have changed into *z*, which then developed into *r* in late Bulgar.

Chuvash words are, as a rule, subject to sound harmony. The vowels of a word normally belong either to the front or to the back class. Most suffixes have a back vowel and a front vowel variant. However, some suffixes of standard Chuvash exist only in a front vowel variant: the plural suffix *-sem*, as in *ača-sem* 'children' (of *ača* 'child'), and the third-person possessive suffix, as in *ïvăl-ĕ* 'her/his son' (of *ïvàl* 'son').

Grammar

The morphology exhibits certain deviations from Common Turkic patterns. There are thus exceptions from the agglutinative principles generally valid for Turkic languages (e.g., *tu* 'mountain' vs. *tăv-a* [mountain-DAT] 'to the mountain') (cf. Turkish *dağ* [mountain], *dağ-a* [mountain-DAT]). Eight cases are normally distinguished for the standard language. As a result of phonetic development, the dative and accusative case markers have fused into one marker, *-A*. Besides the suffixless nominative, the dative–accusative, the genitive in *-An*, the locative in *-rA*, and the ablative in *-rAn*, Chuvash grammarians reckon with an instrumental-comitative case in *-pA*[*lA*], a privative (or abessive) case in *-sAr*, and a causal or purposive case in *-šAn*. Some scholars distinguish still more cases, e.g., a directive in *-AllA*. The plural suffix *-sem* is of unknown origin; other Turkic languages use plural suffixes of the type *-lAr*. The plural

marker *-sem* follows possessive suffixes and precedes case markers (e.g., *kil-ĕm-sen-čen* [house-POSS.1.SG-PL-ABL] 'from my houses'). In other Turkic languages, the plural suffix precedes the possessive markers, as in Turkish *ev-ler-im-den* [house-PL-POSS.1.SG-ABL].

The nominative forms of the personal pronouns of the first and second persons contain a proclitic deictic element *e-*, lacking in other Turkic languages: *epĕ* 'I', *esĕ* 'you (singular)', *epir* 'we', *esir* 'you (plural)' (cf. Turkish *ben*, *sen*, *biz*, *siz*). The reflexive pronouns of the type *xa-* plus possessive suffixes (e.g., *xam* 'I myself') are unknown in other Turkic languages. Three degrees of proximity are expressed with the demonstrative pronouns *ku* 'this', *śak*(*ă*) 'this there', and *śav*(*ă*) 'that there'. The numerals 1–10 display, besides their normal forms (*pĕr*(*e*) 'one', *tăxăr* 'nine'), emphatic variants with long consonants for use in isolated syntagmatic positions (*pĕrre* 'one', *tăxxăr* 'nine'). Ordinals are formed with the suffix *-mĕš*, otherwise unknown in Turkic (*ikkĕ-mĕš* [two-ORD] 'second').

The Chuvash verb system does not exhibit such important deviations from the common Turkic system as has been assumed by some researchers. For example, the so-called 'aorist' (e.g., Turkish *gel-ir* [come-AOR.3.SG] 'comes, will come') is not lacking in Chuvash, but has survived as the so-called future, as in *kil-ĕ* [come-FUT.3.SG] 'will come'. The negated imperative is formed with a preposed particle *an* (*an pĭr* [NEG go.IMP] 'do not go'), whereas other Turkic languages use the negation suffix *-mA* with imperatives as well (e.g., Turkish *git-me* [go-NEG.IMP] 'do not go').

It has been suggested that some of these idiosyncratic Chuvash features – the deictic element *e-*, the pronouns *śakă* and *śavă*, the negative particle *an*, and the plural suffix *-sem* – have been copied from Mari or other Volga Finnic languages.

Lexicon

Most basic words in the Chuvash lexicon belong to the common Turkic vocabulary. Many elements have, however, been copied from other languages, mostly from Tatar, neighboring Finnic languages, and Russian. An old layer indicates contacts with Samoyeds in southwestern Siberia. Later loans reflect the contacts with Mari in the Volga region, e.g., *pürt* 'house' < pört. Tatar dialects have exerted strong influence on the lexicon. Words of Arabic and Persian origin have mostly entered Chuvash via Tatar, but certain words were borrowed already in the Volga Bulgar period. Words of Mongolic origin have also mostly been copied from Tatar, such as *tăxta-* 'to wait' < *tuqta-* 'to stop'. There are numerous Russian loans, including xaśat 'newspaper' < *gazeta* and *kĕneke* 'book' < *kniga*. There are also many lexical elements of unknown origin.

Dialects

Modern Chuvash has two main dialects. Viryal, the 'upper' dialect, is spoken in the northern and northwestern parts of the Republic. Anatri, the 'lower' one, is spoken in the south. In the center and northeast, there is found a transitional dialect that is rather close to the lower dialect. The differences between the dialects are small. Standard Chuvash is based on Anatri dialects. Chuvash speakers living outside the Republic also speak Anatri dialects. Vowel harmony is less consistent in Standard Chuvash and Anatri than in Viryal. Tatar loans are more common in Anatri, whereas Mari and Russian loans are more common in Viryal.

Circum-Baltic Area

M Koptjevskaja-Tamm, Stockholm University, Stockholm, Sweden

© 2006 Elsevier Ltd. All rights reserved.

The Circum-Baltic area comprises primarily Baltic, Germanic, and Slavic languages within Indo-European; Finnic and Saami within Uralic/Finno-Ugrian; as well as the Indo-Aryan language(s) Romani and the Turkic languages Tatar and Karaim. Since time immemorial it has been an arena for intensive linguistic contacts, but it has never been united, either linguistically, politically, economically, or culturally. Following Jakobson, linguists have suggested various partly overlapping Sprachbünde here. However, the notion of Sprachbund is hardly applicable to an area of such historical and linguistic complexity, with many layers of micro- and macrocontacts and mutual influences superimposed on each other over a long period of time.

The Circum-Baltic Area: The Historical, Geographical and Sociocultural Background

The region around the Baltic Sea has been inhabited by man at least since the end of the last glacial era (around 8000 B.C.). In historical times, it has mainly been the home for languages from two linguistic stocks: Indo-European (Baltic, Germanic and Slavic languages) and Uralic/Finno-Ugrian (Finnic and Saami). In addition, three 'exotic' languages have been used in the area for a considerable time: the Indo-Aryan language(s) Romani and the Turkic languages Tatar and Karaim. The exact delineation of the 'Circum-Baltic area' (CB area) and list of the 'Circum-Baltic languages' (CB languages; both terms launched in Dahl and Koptjevskaja-Tamm, 1992 and further developed in Dahl and Koptjevskaja-Tamm, 2001) are open to discussion. At least the following languages can count here (see also Figure 1):

- Indo-European
  - Germanic
    - West: High German, Low German, Eastern Yiddish
    - North: Danish, Swedish, Dalecarlian, Norwegian
  - Baltic: Latvian, Lithuanian
  - Slavic
    - West: Polish, Kashubian
    - East: Belarusan, Russian
  - Indo-Aryan: Romani
- Finno-Ugrian
  - Finnic: Estonian, Finnish, Ingrian, Karelian, Ludian, Olonetsian, Veps

Figure 1 The Circum-Baltic languages. Nonterritorial languages (Romani, Yiddish, Tatar) not shown.

Saami: Southern S., Ume S., Pite S., Lule S., Northern S., Inari S., Skolt S.
Turkic: Karaim, Tatar

The list does not contain extinct languages – e.g., Polabian (Slavic); Old Prussian, Jatvingian, Curonian, and Galindian (Baltic) – and ignores the dialectal variation. Dalecarlian (*egentligt dalmål*), however, is treated here as a separate language, or a chain of languages, as opposed to its traditional inclusion among the Eastern Swedish dialects. 'Dalecarlian' refers to the highly conservative Scandinavian vernaculars that are spoken in the Swedish province of Dalarna (Dalecarlia) and are not comprehensible to speakers of Standard Swedish.

The CB area was settled via numerous migrations; among others, the northward expansion of groups of Indo-Europeans, and much later the Slavic northward expansion to the former Baltic and Finnic-speaking regions. Archaeologists, geneticists, and linguists all claim to trace back the two language stocks in the area at least to the 2nd millennium B.C., even though they disagree on who of the Indo-Europeans or Finno-Ugrians were the first ones where. Finno-Ugrians and Indo-Europeans were engaged in multiple contacts already in prehistoric times, both outside and within the CB area. Some of these contacts must have taken place in extensive bilingual areas; otherwise it is hardly possible to explain the huge number of Baltic and Germanic loanwords in Finnic, including even kinship terms and names for body parts.

Although the CB area has been an arena for intensive contacts since time immemorial, it has never been economically, politically, culturally, or linguistically united. The contacts, both peaceful and military, have been achieved both across the sea and by land. Movements across the sea normally involve fewer people than those on land, either tradesmen, missionaries, warriors, or colonizers, and there is a smaller chance that the newcomers will 'sweep' through the area. Also, coastlines and numerous islands often serve as refuges for the languages pushed from the inland by expanding ones.

The CB area has been constantly divided and redivided among different spheres of influence. Thus, the period of 800–1000 meant expansive activities of the Scandinavian Vikings and the emergence of the Scandinavian, Polish, and Russian states, each with its own sphere of dominance. The period of 1100–1500 witnessed Denmark's expansion, the crusades and the establishment of the Teutonic Order states in Northern Baltikum, the dominance of the Hanseatic league, and the expansion of the Polish and Lithuanian states, later of the Polish-Lithuanian state. In later times, the area went on being repartitioned among powers such as Sweden, the Polish-Lithuanian Commonwealth, Prussia (later Germany), and Russia (later the Soviet Union). Each of the dominant powers brought with it a new prestige language (Danish, Low German, the Eastern Slavic variety used in the Grand Duchy of Lithuania, Polish, Russian, Swedish and German) that expanded over a large area and influenced the local languages. The three main religions in the area – Catholicism, Lutheranism, and Greek Orthodoxy – have also considerably shifted their spheres of dominance over time.

Contact Phenomena within the CB Area

There is an old tradition of studying contacts among the languages around the Baltic Sea which mostly concentrated on loanwords. R. Jakobson (1931/1971) was the first to apply the term 'Sprachbund' to the languages of the CB area. He suggested that several languages spoken around the Baltic Sea together built a 'phonetic' Sprachbund. These included Baltic, two South Finnic languages (Livonian, Estonian), Mainland Scandinavian (except for an area in the west of Norway and for most of the Swedish dialects in Finland and in Estonia), Northern Kashubian, and the Germanic varieties spoken in the Cologne-Trier area (Central Franconian and Limburgian), i.e., outside of the CB area proper. Their common property is lexical, or pitch accent (i.e., tonal oppositions in addition to stress), which in Danish corresponds to the opposition between syllables with and without a glottal closure, *stød*. However, although the CB languages show a very high concentration of lexical accents in Europe, and probably also globally, there is no evidence for any real connections here, primarily, between the Scandinavian languages, on the one hand, and Baltic and South Finnic, on the other hand (Lehiste, 1988; Koptjevskaja-Tamm and Wälchli, 2001).

Later research has suggested several partly overlapping Sprachbünde in the CB area, with two main hotbeds of areal phenomena. The first is the Latvian–Livonian–Estonian zone stretching in different directions over the Baltikum and further – the 'Peipus-Bund' (Décsy, 1973); the 'Baltischer Sprachbund' (Haarmann, 1970; 1976); the 'Convergence zone in the Baltikum' (Stolz, 1991; see also Falkenhahn, 1963); and the second is the Eastern Finnic–Northwestern Russian (–Baltic) core – the 'Eastern Baltic Sprachbund' (Mathiassen, 1985a, 1985b) and the 'Karelian Sprachbund' (Sarhimaa, 1999).

The core in each zone has been a mixed bilingual or multilingual area over long periods of time with complex local contacts leading to assimilation, acculturation, language convergence and/or language shifts. Thus, a strong Finnish substrate is generally

recognized in Latvian, especially in its northeastern dialects, covering the area originally inhabited by Livonians. Livonian itself is at present spoken by a few dozen speakers and is largely influenced by Latvian. Northern Russian has a number of features generally attributed to the Finnic substrate and, primarily, to contacts with the smaller Finnic languages (Ingrian, Karelian, Ludian, Veps, and Votian). The latter languages are now on the verge of extinction or, in the case of Karelian, are mainly used as one part in bilingual mixed codes (Sarhimaa, 1999).

In addition, the CB area partially overlaps with two other suggested convergence zones including, first, Scandinavian–Celtic–Northern Finnic–Saami–the 'Wikinger-Bund' (Haarmann, 1976), and second, Polish–Kashubian–Belarusan–Ukrainian–Lithuanian–the 'Rokytno-Bund' (Haarmann, 1976), or the 'Baltic-Slavic contact area' (Wiemer, 2004; see also Falkenhahn, 1963).

The abundance of different Sprachbünde in the CB area rests partly on a fairly vague understanding of the term. The CB area shows many layers of micro- and macrocontacts and mutual influences superimposed on each other over a long period of time, and the term 'Sprachbund' hardly does justice to an area of such historical and linguistic complexity (Nau, 1996; Koptjevskaja-Tamm and Wälchli, 2001).

The crosslinguistically most striking isoglosses in the CB area are mainly found in its eastern part and include the following (for details, see Koptjevskaja-Tamm and Wälchli, 2001).

1. The alternation between the accusative and the genitive (in Baltic and Slavic) or the partitive (Finnic) case marking differentiates between high transitivity and low transitivity objects, or 'total' vs. 'partial' objects. The details and the relevance of this distinction are subject to a considerable crosslinguistic variation, where Finnic and Standard Russian show the most vs. the least grammaticalized system. The factors underlying this distinction include polarity of the clause (affirmative vs. negative), as in example (1) from Polish, aspect, affectedness of the object, etc. *see* also **Partitives**.

(1) Polish
a. Widzi-my **gwiazd-ę.**
see.PRES-1PL ***star***-ACC
'We see a/the star.'
b. Nie widzi-my **gwiazd-y.**
NEG *see*.PRES-1PL ***star***-GEN
'We do not see a/the star.'

2. Less canonical subjects can sometimes be marked with the genitive (in Baltic and Slavic) or the partitive (Finnic) case. Again, the most grammaticalized system is found in Finnic, where the partitive case consistently marks subjects in existential clauses, as in example (2) from Finnish, and in semantically related clause types. The partitive case is particularly preferred if the clause is negated and the subject refers to a quantitatively nondelimited entity. Roughly the same two conditions govern the choice between the nominative and the genitive case marking on Baltic and Slavic existential subjects, but on a significantly more restricted scale, with the most grammaticalized distinction found in northwestern Russian.

(2) Finnish
a. **Kirj-at** o-vat pöydä-lla.
book-NOM.PL *be*.PRES-3PL *table*-ILLAT
'The books are on the table.'
b. Pöydä-llä o-n **kirj-oja.**
table-ILLAT *be*.PRES-3SG ***book***-PART.PL
'There are (some) books on the table.'

3. In several constructions in Finnic, Baltic and Northern Russian (both Old Northern Russian and modern northwestern dialects), the object appears in the nominative case and not in the accusative. One common context, illustrated in example (3) from northwestern Russian dialects, is provided by an infinitival clause functioning as the subject of a necessitive matrix predicate. The Latvian correspondence to such clauses involves the so-called Debitive Mood, also with the object in the nominative. The set of nominative–object constructions differs greatly across the languages. Thus, while nominative objects in Northern Russian and Lithuanian are normally restricted to clauses with clearly nonfinite predicates (infinitives and converbs), Finnic requires, in addition, nominative objects in imperative clauses and clauses with impersonal passives. It has been suggested that the common denominator of all these contexts is their systematic lack of an overt personal subject (Timberlake, 1974).

(3) Northwestern Russian dialects
a. Topim **pečk-u.**
heat.PRES.1PL ***oven***-ACC
'We are heating the oven.'
b. Nado/ Pora topit' **pečk-a.**
it-is-necessary/ it-is-time heat.INF ***oven***-NOM
'It is necessary/It is time to heat the oven.'

4. Finnic, Baltic, and Slavic display double (or sometimes multiple) options in the case marking of predicate adjectives and nominals. The choice between the nominative and some oblique case, e.g., the instrumental in example (4) from Lithuanian, can roughly be described as correlating with the distinction between time-stable and temporary situations respectively (Stassen, 2001).

(4) Lithuanian
a. Jis yra **mokytoj-as.**
he.NOM *is* ***teacher***-NOM
'He is a teacher.'
b. Jis buvo **mokytoj-u.**
he.NOM *was*.3SG ***teacher***-INSTR
'He was (working as) a teacher.'

5. In Finnic and most Slavic, most cardinal numerals higher than one alternate between case-governing and agreeing with their complements under well-defined syntactic conditions. As example (5) from Russian shows, when the numeral is in one of the direct cases (nominative or accusative), the complement appears in the genitive (or in the partitive in Finnic). Otherwise, both the numeral and the complement are in the same case (here, in the dative). In Baltic, the two properties are primarily associated with different sets of numerals, which is more common both crosslinguistically and within Indo-European.

(5) Russian
a. Ja vižu **pjat'** **stakan-ov.**
I.NOM *see*.PRES.1SG ***five***.NOM/ACC ***glass***-GEN.PL
'I see five glasses.'
b. Ja priš-l-a **s** **pjat'-ju** **stakan-ami.**
I.NOM come-PAST-F.SG ***with*** ***five***-DAT ***glass***-DAT.PL
'I came with five glasses.'

6. Estonian, Livonian, Latvian and Lithuanian use special 'evidential' verb forms for marking that the speaker's factual claims are based on indirect evidence, rather than on direct, or attested evidence (evidential, quotative, relative or oblique mood). These are basically nonfinite verb forms, primarily participles, sometimes 'frozen' in an oblique case: thus, *-vat* in example (6) from Estonian is historically the partitive case form of the present participle.

(6) Estonian
Sina **rääki-vat** saksa keel-t.
you(SG).NOM *speak*-QUOT *German language*-PART
'You are said to speak German; they say you can speak German.'

An isogloss connecting Scandinavian, Baltic, and East Slavic languages is the expression of certain verbal voice functions (reflexive, reciprocal, anticausative, passive) by means of verbal postfixes, i.e., affixes in the last position of a word, following, e.g., tense/aspect and agreement markers. These affixes have all developed due to coalescence between the main verb and permutable reflexive and reciprocal pronouns (*-s/-st* in Scandinavian, *-s* in Baltic, and *-s'/-sja* in East Slavic).

Conclusion

Significantly, there are no isoglosses covering all the CB languages; moreover, the isoglosses pick up different subsets of the languages, in many cases also extending outside of the CB area proper. In the CB area, convergence works primarily on a microlevel and reflects language contacts of groups of people and, maximally, of two or three languages. Convergence comprising more than two or three languages seems always to be the result of the overlapping and superposition of different language contacts. In some respects, the CB region forms a border zone between the Central Eurasian languages in the east and the Standard Average European languages in the west.

Cladistics

A McMahon, University of Edinburgh, Edinburgh, UK

Cladistics is an approach to classification initially introduced for animals and plants. When we consider how close two or more species are to one another, 'close' can mean two different things. In a phenetic classification, what matters is surface similarity: this might mean what animals look like, or how they behave. Phenetic methods seek to measure the distance between species, regardless of cause. Cladistic classifications, however, are based on identifying natural groups, which share characters derived from a common ancestor. Cladistics therefore seeks to recover the shared history of a group of organisms.

Three dangers occur in cladistic classification that are less problematic for phenetics.

- The same character might arise in two or more species by convergent evolution: often, this means the same environmental pressures have led to parallel solutions. Animals with white coats in winter do not necessarily share a single, recent common ancestor; but they probably live in similarly cold conditions for part of the year. Several different mutations may also lead to the same endpoint in different species, especially if systems are intrinsically limited in permitted variability: in DNA, there are only four bases (A, C, G, and T), so that over a long period, multiple mutations at the same site may well result in a C, regardless of starting states and histories. Both forms of convergence are known as homoplasy.
- Contemporary species may also exhibit shared retentions from a distant common ancestor. If several groups have lost a feature, it may be taken as indicating greater closeness than is historically the case between the groups that happen to retain it. For example, egg-laying has been retained in both monotremes (like the duck-billed platypus) and birds; but this tells us nothing about the closeness of the historical relationship between the two groups. Monotremes, historically speaking, are definitely mammals, though other mammals no longer lay eggs.
- The final difficulty does not generally hold at the species level, but at the population level. Within a species, interbreeding between groups and consequent genetic interchange can lead to shared features, though these are a result of recent history, not signals of common ancestry.

Cladistics, because it seeks explicitly to recover the histories of groups, cannot treat all features as equal, since it would then be calculating distance only, and would fall prey to the difficulties outlined above. Instead, it is essential to identify and prioritize shared, derived features, or synapomorphies.

Both cladistic and phenetic methods can be relevant to language. In constructing family trees, we are doing cladistics, since here we attempt to prioritize shared, derived linguistic features. Typological comparison, on the other hand, is essentially phenetic, if the distribution rather than the source of features is the main issue. When conducting cladistic language classifications, it is important to remember the three problems raised above for biological cladistics, since in language too we face homoplasy, or parallel developments; shared retentions in some languages that have been lost in others; and borrowing. It follows that linguistics may also benefit from the investigation and adoption of computational methods

Herbert H. Clark has been one of the most important psychologists within the community of linguists, psychologists, and other cognitive scientists interested in language use. His influential research, pursued with a number of colleagues over the years, has focused on the role of shared knowledge in linguistic communication and has been extremely important within his core fields of psychology of language and psycholinguistics. In addition, connections with Stalnaker's notion of Common Ground and analysis of presupposition (Stalnaker, 1974, 1978) helped his work to become influential in semantics and pragmatics (e.g., Heim, 1982); meanwhile, his interest in detailed analyses of interaction brought his work into close contact with discourse analysis.

Clark did his undergraduate work at Stanford and his graduate work at Johns Hopkins, receiving his Ph.D. in 1966. He briefly taught at Carnegie Mellon before returning to Stanford in 1969, where he has been Professor of Psychology since 1969. He has spent time as a visiting scholar at University College, London, and the Max Planck Institute for Psycholinguistics in Nijmegen.

Class Language

A Luke, Nanyang Technological University, Singapore
P Graham, University of Waterloo, Canada

The relationship between language and social class is a key theoretical and empirical issue in critical discourse studies, ethnography of communication, and sociolinguistic research. It has been a focal point for postwar and current policy in language planning, and language and literacy education. The central questions of a class analysis of language were stated in Mey's (1985) proposal for Marxian pragmatics: 'Whose language' counts? With what material and social consequences? For which communities and social groups? Central concerns are how language factors into the intergenerational reproduction of social and economic stratification, and how communities, families, schools, the media, and governments contribute to "linguistic inequality" (Hymes, 1996). Yet current research continues to table and debate contending definitions of language and social class as social and economic phenomena.

Marx viewed language as an intrinsic characteristic of human 'species being,' as a form of mental and material labor. The "language of real life," he argued, is "directly interwoven" with "material activity and... mental intercourse" (Marx and Engels, 1845/1970: 118). This "mental production" is "expressed in the language of politics, laws, morality, religion, metaphysics etc. of a people." 'Sense experience,' the work of the eye and ear, was the basis not only of science, but of communal and social life (Marx, 1844/1964: 160–166). At the same time, Marx's (Marx and Engels, 1845/1970: 37) classical definition of ideology as a 'camera obscura' established the centrality of language in the distortion and misrepresentation of social and economic reality in social class interests (*see* **Marxist Theories of Language**).

Marxist theory establishes three critical traditions in the analysis of language and class. These are: (1) the analysis of language as a form of class-based social action and consciousness; (2) the analysis of social class and linguistic variation; and (3) the analysis of language as the medium for power and control, ideology, and truth in specific linguistic and capital markets (*see* **Power and Pragmatics**).

Language as Social Action and Class Consciousness

The prototypical class analysis of language was undertaken by Voloshinov (1973) (*see* **Voloshinov, V. N. (ca. 1884/5–1936)**). Language was conceptualized as a marker of class consciousness and a medium of class struggle. According to models of heteroglossia and 'multivocality,' each utterance and text is a revoicing of previous historical speakers and writers. The ideological content and social functions of each speech act or speech genre bear their own material historical origins. That is, they are produced and reproduced by and through social and economic "conditions of production" (Fairclough, 1992). By this account, face-to-face language exchanges are instances of class conflict and ideological difference, where class-located social actors bring to bear distinctive material interests and discourse positions. The point of such analysis is to extend the notion of the situated speaking and writing subject, to a closer sociological and economic analysis of that positionality. Contemporary work in critical discourse analysis supplements class analysis with attention to the linguistic construction of gender, race, sexual preference, and other forms of social identity ideology, and position (e.g., Lemke, 1995).

If utterances and their use are indexical of ideology and social class consciousness, what might this mean for differing cultural groups, communities, and their historical practices? Following Vygotsky (*see* **Vygotskii, Lev Semenovich (1896–1934)**), Luria (1982) argued that the cognitive uses of the 'tool' of language were mediated by one's social relations, cultural practices, and material conditions. In his studies of the Uzbeks, Luria made the claim that particular forms of cognition and consciousness, what Marx referred to as capacity for the "production of ideas," were linked to cultural practices and material conditions of tool use. The cognitive affordances of language and literacy are mediated by material economic and social conditions, including class location and cultural history.

In contemporary literacy theory, Paulo Freire also argued for the direct links between language and social class consciousness. Freire's (1972) prototypical work was concerned with the effects of literacy education upon the language and consciousness of the indigenous population and peasantry of postwar Brazil. Bringing together Marxist dialectics with liberation theology, he argued that autocratic governments and education systems constituted "cultures of silence" where marginalized populations were educated in ways that misnamed and misrecognized the world. Freire's work views ideologically distorted language as a mode of class-based false consciousness.

For Freire, critique of class consciousness was achieved through an educational process of 'renaming'

the world in ways that demystified power, consciousness, and life, a similar agenda to that of Mey (1985), Chouliaraki and Fairclough (2001) and other contemporary critical linguists. Current agendas for the teaching of 'critical literacy' and critical discourse analysis stand in this Marxist tradition, focusing on the demystification, critique, and reconstruction of ideological language (Luke, 2004).

Linguistic Variation and Social Class

A further concern in the analysis of language and social class is how language variation acts as a marker and instrument of social class, and of racial and other forms of social stratification. A principal concern of sociolinguists in the postwar period has been over the effects of the differential and inequitable spread of economic and social capital on the language minority, postcolonial, and economically marginal communities (Hymes, 1996) (*see* **Minority Languages: Oppression**). The postwar origins of language planning reflect the impact of colonization, decolonization, migration, and geopolitical conflict upon linguistic retention and stability. The flow of global, regional, and national capital visibly impacts upon language loss, use, and retention (Pennycook, 1998). In the postwar period, sociolinguistic and language planning research has engaged with the effects of the unequal spread and distribution of economic capital upon language loss. Yet attempts to theorize and empirically describe the complex reproductive relationships of language and social class have been debated and contested (*see* **Linguistic Decolonization**).

The sociological and sociolinguistic research on U.K. children by Basil Bernstein and colleagues (e.g., Bernstein, 1975) took up this challenge. This work provided an account of the role of language in the institutional production of stratified levels of educational achievement. Bernstein's argument was that working class students spoke a "restricted code," characterized by embedded and literal meanings, limited command of deixis, and thresholds in technical complexity. Middle-class children, he argued, mastered an "elaborated code" which was fitted for educational success and mastery of academic and scientific discourses. These, he argued, were tied to particular forms of early childhood language socialization and family structure (Bourdieu and Passeron, 1992). Bernstein's work was the object of several decades of controversy. Labov's (2001) studies of urban African-American language registers and nonstandard dialects, and Heath's (1983) studies of early class-based language socialization made the case against models of linguistic deficit. Bernstein's model has been defended by systemic functional linguists, who argue that there are indeed elaborated technical registers and contents, specific language domains affiliated with power, some of which particular social classes make explicitly available in early language socialization and educational training (Hasan and Williams, 1996) (*see* **Codes, Elaborated and Restricted (Bernstein)**).

As distinctive sociodemographic speech communities, particular social classes may indeed have different speech patterns, varying in lingua franca, register, dialect, accent, and practices of diglossia (*see* **Multilingualism: Pragmatic Aspects; Register: Overview**). These, further, are affiliated with class-based social ideologies and cultural practices (Fishman, 1991). Ethnographic studies have shown how these variations are made to count in local social networks and institutions (Milroy, 1987). But the social and cultural bases and material consequences of such differences remain localized and contentious. To move past descriptive claims requires a broader sociological theory of social class, of "linguistic markets" (Mey, 1985; Bourdieu, 1992), and of changing media and modes of production and information.

Language as Capital in Linguistic Markets

Classical sociological definitions of social class begin from conceptions of structural economic location and material position. They attempt to define position and power *vis-à-vis* dominant means of production. The tendency of Marxist models is to further affiliate social class with particular 'class consciousness,' of which language, its use and its expression, is a constitutive speech marker. Bourdieu's (1992) sociology began from a view that class position is at least in part structurally determined. But it is also embodied by human subjects in their 'habitus,' the sum total of socially acquired dispositions.

By this account, the bodily performance of linguistic competence is an element of cultural capital. This capital and affiliated forms of embodied taste, style, and ideology, constitute a key marker of one's social class position and mobility. Linguistic capital is deployed in specific social fields, which constitute 'linguistic markets.' Each market, each institutional context, in turn has variable rules and conventions of exchange whereby linguistic competence and literate proficiency in specific languages is valued or not. There, language use – as class marker and tool – has exchange value and power only in relation to other forms of capital, including social capital (e.g., networks, institutional access), economic capital, formal institutional credentials, artifacts, and so forth.

This is a more complex view of the relationship of language and social class. Language matters, as a primary marker of class, gender, culture, training, education, networks, traditions, and ideological consciousness. Yet like post-structuralist theories of discourse, Bourdieu's model viewed language not just as an index or marker of class position, but as reflexively constituting position and identity, power, and categorical social status. In this way, how language marks class, capital, and power is sociologically contingent, rather than determined by the characteristics of linguistic code or class position per se, or the ostensive power of any given utterance, genre, or text (Luke, 1996). This contingency is dependent on the availability of other forms of capital, and the variable, historically shifting norms, rules, and conventions of particular social institutions, fields of knowledge, and linguistic markets (*see* **Discourse, Foucauldian Approach; Poststructuralism and Deconstruction; Structuralism**).

Current Issues

One of the principal critiques of postwar sociolinguistics, ethnography of communication, and functional linguistics was that they lacked a sufficient analysis of power, capital, and conflict. Indeed, sociolinguistic models of 'social context,' 'context of situation,' and 'social network' are often based on structural functionalist models of society and culture. The study of language and social class requires the rigorous analysis of social and economic relations within and between speech communities. Current work on language and social class continues to examine how language represents class consciousness, how it is implicated in ongoing issues of class conflict and cohesion, and how its acquisition and use are central to intergenerational production of social stratification of material and discourse resources.

Language variation, diversity, change, and ideology can be systematically linked to social class. Linguistic performance in text and discourse production does indeed have both symbolic and material exchange value, particularly in service- and information-based economies. But this depends upon the complex local economic and institutional formations of particular speech communities. Bourdieu offered a stronger analytic frame for analyzing how language 'counts' in specific institutional, disciplinary, and knowledge fields, and everyday social contexts. He suggested that issues around 'whose language' counts, which classes have power, require a rigorous socioeconomic analysis. Particularly under conditions of late capitalism and globalization, these sociological and sociolinguistic contexts and conditions are under considerable historical transition and challenge.

As the medium of consciousness and labor, language is entailed in the production of ideology, material goods, and social relations. The move in globalized economies towards information- and discourse-based forms of labor raises a number of key challenges to linguistic and ethnographic studies. First, linguistic, semiotic, and discourse competence will have increased significance in productive labor and consumption, shifting social class relations to means of production. Second, social class location and membership is determined by relations to dominant modes of communication, semiosis, and information (Castells, 2000) as much as it might be defined in classical Marxist terms. Finally, the formation of social class identity, ideology, and speech community have become more complex. They are now strongly influenced by forces of mass culture, media, and globalized information flows.

One of the principal claims of post-structuralist and postmodern theory of the past decade has been a breakdown of essential relationships between discourse and social class as a primary analytic category. It is increasingly difficult to analyze social class formation without due consideration of the complexity of cultural, racial, gender, and religious identity and position. Any analysis of language and social class must engage with this complexity. But indeed, any contemporary analysis of class and intersecting categories must engage with the constitutive place of language, text, and discourse.

Classical Antiquity: Language Study

D J Taylor, Lawrence University, Appleton, WI, USA

© 2006 Elsevier Ltd. All rights reserved.

As is the case with so many other Western intellectual endeavors, the formal study of language begins in ancient Greece and is transmitted to the modern world by the Romans, but only after the latter have creatively adapted and transformed the linguistic legacy bequeathed to them by their Greek predecessors. The original historical context is the dynamic symbiosis of philosophical speculation and literary experimentation that characterized and helped to define the golden age of classical Greece, but that context changed dramatically over the centuries and ranged from the scholarly ambience of Alexandria to the bilingual reality of Constantinople and from the fledgling philology of early Rome to the monumental tradition of the late Latin *artes grammaticae*. Graeco–Roman language science features numerous noteworthy accomplishments: the obligatory inclusion of vowels in the alphabetic inventory, an achievement of momentous import for the development of literature; the enumeration of four illocutionary forces, what they called sentence-types; the invention of and reliance upon the four *pathē* or transformations (addition, deletion, substitution, permutation) as both heuristic procedures and explanatory devices; the coining of an entire metalanguage (much of which is still in use) to refer to the hundreds of grammatical phenomena they discovered; the canonical definitions of the parts of speech; carefully composed and cogent arguments on the arbitrariness of language and the relationships between *signifiant* and *signifiée*; meticulous and copious descriptions of accidence including, in the case of the Romans, the discovery and identification of the declensions and conjugations that form the keystone of all subsequent Latin grammatical treatises and textbooks; the publication and widespread dissemination of linguistic knowledge throughout both the Greek and Roman worlds via grammatical manuals (*technai*) and tomes (*artes*); and in general the conscious acknowledgment of, and emphasis upon, the central and ubiquitous role of grammar in education and intellectual discourse as well as an unremitting insistence upon scientific rigor in linguistic exegesis. So classical linguistics is much more familiar to modern language scientists than might at first be supposed.

Historiographical Problems

The lamentable loss of so much of ancient grammatical literature has made it difficult to chronicle accurately the course of classical language science: no Stoic linguistic treatise is extant; the dating and authorship of the only surviving Alexandrian grammatical manual have been questioned for centuries; almost all of ancient Rome's early scholarly forays into the study of the Latin language, i.e., Aelius Stilo's

As is the case with so many other Western intellectual endeavors, the formal study of language begins in ancient Greece and is transmitted to the modern world by the Romans, but only after the latter have creatively adapted and transformed the linguistic legacy bequeathed to them by their Greek predecessors. The original historical context is the dynamic symbiosis of philosophical speculation and literary experimentation that characterized and helped to define the golden age of classical Greece, but that context changed dramatically over the centuries and ranged from the scholarly ambience of Alexandria to the bilingual reality of Constantinople and from the fledgling philology of early Rome to the monumental tradition of the late Latin *artes grammaticae*. Graeco–Roman language science features numerous noteworthy accomplishments: the obligatory inclusion of vowels in the alphabetic inventory, an achievement of momentous import for the development of literature; the enumeration of four illocutionary forces, what they called sentence-types; the invention of and reliance upon the four *pathē* or transformations (addition, deletion, substitution, permutation) as both heuristic procedures and explanatory devices; the coining of an entire metalanguage (much of which is still in use) to refer to the hundreds of grammatical phenomena they discovered; the canonical definitions of the parts of speech; carefully composed and cogent arguments on the arbitrariness of language and the relationships between *signifiant* and *signifiée*; meticulous and copious descriptions of accidence including, in the case of the Romans, the discovery and identification of the declensions and conjugations that form the keystone of all subsequent Latin grammatical treatises and textbooks; the publication and widespread dissemination of linguistic knowledge throughout both the Greek and Roman worlds via grammatical manuals (*technai*) and tomes (*artes*); and in general the conscious acknowledgment of, and emphasis upon, the central and ubiquitous role of grammar in education and intellectual discourse as well as an unremitting insistence upon scientific rigor in linguistic exegesis. So classical linguistics is much more familiar to modern language scientists than might at first be supposed.

Historiographical Problems

The lamentable loss of so much of ancient grammatical literature has made it difficult to chronicle accurately the course of classical language science: no Stoic linguistic treatise is extant; the dating and authorship of the only surviving Alexandrian grammatical manual have been questioned for centuries; almost all of ancient Rome's early scholarly forays into the study of the Latin language, i.e., Aelius Stilo's

linguistic analyses of archaic documents, Varro's voluminous corpus, and Palaemon's grammar, are lost; and in extant Roman *artes*, references to otherwise unknown grammars and grammarians are all too frequent. The tendency to ascribe various notions and developments to nonexistent texts and anonymous authors is therefore one of several historiographical problems posed by the vast lacunae in our knowledge. Dichotomies of one sort or another for which there is little evidence abound in the secondary literature – nature and convention, analogy and anomaly, philosophical and technical grammar – and are adduced to provide theoretical links between extant and lost texts in order to chart a cumulative course for the history of grammatical thought in antiquity. More recent research, however, has concentrated exclusively on extant texts and what can be known for sure, has uniformly eschewed weighty and sweeping generalizations, and has concluded that the history of Graeco–Roman linguistics is for the most part a discontinuous one. Episodic such accounts may be, but they are at least faithful to the historical record. Despite the many problems, readable and informative surveys of classical linguistics do exist, e.g., Della Casa (1973), Pinborg (1975), Baratin & Desbordes (1981), Hovdhaugen (1982), Robins (1990), Schmitter (1991), Law (2003).

Such surveys readily reveal that linguistic information can be found almost anywhere, for philosophers, logicians, rhetoricians, historians, philologists, literary critics, even poets, as well as bona fide grammarians, contribute to formulating ancient language science. Moreover, Greeks and Romans neither compartmentalize knowledge nor always broker out grammatical phenomena as we do. They do, however, create a vast array of technical terms, but that terminology is, for much of the time, in the process of evolving and does not become fixed until late in the tradition; consequently many authors employ the language of everyday intellectual discourse, often embellished by notable metaphors, rather than an established metalanguage when articulating their linguistic theories and practices. So both the availability of texts and the contents of those texts pose historiographical problems of some magnitude. What the Greeks and Romans have to say about language and the study of language in those texts is, however, significant and ranks as one of the major intellectual legacies bequeathed to us by classical antiquity. They do, after all, construct the classical foundations of most subsequent language science, and so we can observe firsthand the Western world's earliest attempts to describe scientifically and to study formally what is uniquely human, namely, language. We can also, of course, find striking anticipations of and parallels with later, even modern, linguistics, but we can also encounter equally striking differences in both intellectual attitudes and approaches to the analysis of linguistic phenomena.

From the Origins to Plato and Aristotle

Including vowels in the Semitic alphabet that the Greeks imported and adapted was a stroke of genius and, *inter alia*, allowed the Greeks to commit Homer's orally composed *Iliad* and *Odyssey* to writing. The two processes established the foundation of language science in Greek antiquity, and as a consequence literature enjoys forever a privileged status in the scientific study of language. As literature proliferates, 5th-century Greeks attend consciously to differences in dialect and meter and to errors in morphology (barbarisms) and syntax (solecisms). Protagoras initiates what becomes a hallmark of Greek linguistics, namely, taxonomy: he distinguishes three genders, three numbers, and probably the four *pathē* or transformations; he also identifies four sentence-types (wish or prayer, question, answer, command). Herodotus informs us of an Egyptian experiment to determine the original language, but both monogenetic and polygenetic theories on the origin of language(s) are known. Socrates addresses the existential and equational functions of the copula and the arbitrariness of the sign. The scores of etymologies and the explicit confrontation of conventional and natural explanations for names in the *Cratylus* have attracted far more attention than one would suppose, and the dialogue has its fair share of both critics and admirers. The term *ptōsis* ('inflected form' and later 'case') also appears, but the relationship between its etymological meaning ('a fall or falling') and its grammatical meaning is still puzzling. Plato analyzes and classifies the sounds of Greek reasonably effectively and also establishes once and for all the roles of NP and VP in linguistic thought, though the key passage (*Sophist* 261D–263D) is quite vexing. He begins by referring to *onomata* 'nouns' and *rhēmata* 'verbs' as individual entities but then abruptly treats them in combination as necessary sentential constituents, presumably therefore as 'subjects' and 'predicates'; yet nowhere does he employ *onoma* as 'subject' or *rhēma* as 'predicate.' Nonetheless, he has both defined noun and verb and postulated a fundamental, binary, syntactic structure that necessarily includes the former in one part and the latter in the other. So by the mid-4th century, grammatical knowledge is fairly extensive but also fairly eclectic.

The grammatical sketch in Aristotle's *Poetics* (21) takes us into the realm of more formal linguistic analysis and probably into the schoolroom as well.

Aristotle reprises much of what we already know from Plato but organizes and augments it. He divides letters into vowels, semivowels, and consonants (mutes), and he correctly identifies aspirated stops for the first time. He then defines and describes syllable, conjunction, article, noun, verb, cases (inflected forms of both nouns and verbs), and discourse or speech. These contents clearly manifest an organizational scheme that ultimately becomes traditional in both grammar and education: a hierarchical arrangement of linguistic items (letters, syllables, words, sentences), an embryonic account of selected parts of speech (although, conspicuously, Aristotle does not use and presumably does not know that term), and a rudimentary description of nominal and verbal accidence. Aristotle affirms the conventional view of language, the uniqueness of human language (as opposed to animal sounds), and the priority of speech over writing; formulates more precise definitions by including the feature 'minus tense' in his definition of noun and 'plus tense' in that of the verb; defines metaphor as a semantic *analogia* 'proportion, analogy'; provides a fairly sophisticated and semisyntactic treatment of solecisms; offers better-developed notions of subject and predicate; and formulates a list of ten predicate-types that is as exhaustive as it is ignored by later grammarians. Aristotle's analysis of predicates may not be unrelated to his four parts of speech, for an Aristotelian categorical syllogism essentially requires only nouns, articles, verbs, and conjunctions (his rather open-ended category that includes logical connectors). Aristotle's remarks on innateness strikingly anticipate modern theories that postulate a universal mental language common to all humankind. Greek language science has obviously progressed and expanded its scope of inquiry during the classical period.

Hellenistic Linguistics

The Hellenistic Age (3rd–1st centuries B.C.) features Stoic logic and Alexandrian philology: the former introduces what passes for syntax throughout most of classical antiquity, and the latter establishes literary criticism as the 'noblest part' of grammatical inquiry. Our major sources for Stoic logic, Diogenes Laertius and Sextus Empiricus, are both late (also confused and polemical respectively), and the Alexandrian *Technē* ascribed to Dionysius Thrax may not be completely authentic. It was, however, a remarkably productive period in the history of classical linguistics.

Stoics divide their epistemology into logic (dialectic) and rhetoric and the former into the study of *phōnē* 'sound' and *to sēmainomenon* 'the being signified.' Stoics therefore define language science properly as the relationship between sound and meaning. Under *phōnē* they analyze sounds, letters, parts of speech, grammatical errors (barbarisms and solecisms), poetic diction, verbal ambiguities, euphony, and music; under *to sēmainomenon* they study case, voice, mood, and *lekta* 'sayables.' They increase the number of parts of speech by adding articles and maybe adverbs and by differentiating common and proper nouns, + or – case becomes a defining feature of the major parts of speech, the cases are identified and named, and grammatical terminology proliferates. Arguably the Stoics' most sophisticated linguistic achievement is their analysis of aspect and tense in the Greek verb system, but where and exactly how they do so are still *sub iudice*. Stoic logic privileges *to sēmainomenon*, and the increase in the number of parts of speech is due to the emphasis on logic and *lekta* rather than to any cumulative process or more refined taxonomy.

Lekta, the things signified, are to be distinguished from both the things signifying (sounds) and the things existing (referents); the former are incorporeal, but the latter two are corporeal. Referents aside, logicians often distinguish declarative statements, which can be written or spoken and read or heard and which are therefore corporeal, from propositions, which are what the statements mean or express and which are consequently incorporeal. *Lekta* are either complete or incomplete. Complete *lekta* are yes–no questions, questions requiring a declarative answer, commands, oaths, and, most significantly, propositions (*axiōmata*), i.e., statements that can be affirmed or denied. Stoic logic is therefore propositional logic, and Stoic syntax is the syntax of propositions. Our sources discuss the several types of *axiōmata* and their syntax at length. Incomplete or deficient *lekta* include predicates and, although no text explicitly says so, probably subjects. The Stoic analysis of predicates distinguishes clearly and unambiguously between the incorporeal predicate (*katēgorēma*) and the corporeal verb (*rhēma*) and accordingly treats the former under *to sēmainomenon* and the latter under *phōnē*. Both the structure and the metalanguage of Stoic logicolinguistic thought are remarkably consistent. The complete absence of original Stoic linguistic texts from the historical record is one of the most lamentable losses in intellectual history.

Alexandrian scholars are first and foremost philologists and literary critics: Aristophanes of Byzantium produces epoch-making editions of the *Iliad* and *Odyssey*; Aristarchus invents critical symbols for indicating doubts about the authenticity, repetition, or order of verses, and introduces respect for the authority of manuscript traditions into the history of

scholarship; and Dionysius Thrax becomes famous for his lectures on Nestor's cup (*Iliad* 11.632–37). Numerous commentaries, lexicographical treatises, etc., facilitate and enhance the reading of the now critically edited texts of classical Greece's monumental authors. Though no textbooks are extant, the study of language and literature is obviously at the core of the educational curriculum.

Critical editions and ancillary scholarly texts presuppose a vast reservoir of grammatical knowledge, but whether such knowledge is ever pursued for its own sake is still in dispute. For example, Aristophanes supposedly authors a treatise entitled *Peri Analogias* and adduces five principles, to which Aristarchus adds a sixth, for determining analogy, and so some scholars argue that the Alexandrians actually formulate rules for inflection, declensions, conjugations, paradigms, etc. Yet no extant text contains anything of the sort, and so other scholars argue that the criteria for analogy are much more readily understandable as criteria for emending texts. As Aristotle uses *analogia* as a means of identifying and defining metaphor, so the Alexandrians employ it as a heuristic procedure for correcting poorly transmitted manuscripts. Moreover, no extant Hellenistic text, grammatical or otherwise, testifies to any sort of analogy/anomaly quarrel between Alexandrians and Stoics, as was once supposed. The Alexandrians do, however, dramatically expand the scope of grammatical inquiry in their drive to edit and comprehend literary texts, but unfortunately the one extant grammatical *Technē* that purportedly summarizes their accomplishments in language science raises more questions than it answers.

Both the authorship and the dating of the *Technē Grammatikē* have been questioned for centuries (see Di Benedetto, 1958–59, 1973; and Law and Sluiter, 1995). Moreover, neither the *Technē* nor its author receives contemporary acclaim, and both are more influential later and elsewhere. The text begins as follows (translation from Kemp, 1986):

> Grammar is the practical study of the normal usages of poets and prose writers. Its six divisions comprise: (1) skill in reading (aloud) with due attention to prosodic features; (2) interpretation, taking note of the tropes of literary composition found in the text; (3) the ready explanation of obscure words and historical references; (4) discovery of the origins of words; (5) a detailed account of regular patterns; and (6) a critical assessment of poems; of all that the art includes this is the noblest part.

Dionysius or whoever is clearly thinking of grammar in philological and literary terms. After four brief entries on the first topic, the text switches abruptly to an analysis of letters and syllables, defines word and sentence, then enumerates eight parts of speech, and thereafter devotes itself wholly to defining and exemplifying those parts of speech; none of this (except the four items on reading aloud) follows from any of the six divisions listed in the introductory paragraph. Scholars account for this inconcinnity of contents by assuming that the first five paragraphs are genuine and the remainder spurious. In any case, the contents of the slim volume are hardly exceptional, offering little or nothing beyond the ken of any competent Hellenistic grammarian.

Aristotelian categorical and Stoic propositional syllogisms no longer determine the enumeration of the parts of speech; so Alexandrians are free to focus on the parts of speech (or, more properly, parts of the sentence) in normal literary discourse and therefore arrive at eight such items. The *Technē*'s parts of speech are noun (including both common and proper nouns), verb, participle, article, pronoun, preposition, adverb, conjunction, and this list becomes canonical. The author is addicted to semantic taxonomy – he classifies nouns into 24 subtypes, adverbs into 26, and conjunctions into eight, all on the basis of meaning – but he describes grammatical accidence rather skillfully. The plethora of grammatical terms is impressive: the tiny volume contains about 150 technical terms that will comprise almost the entire Western linguistic vocabulary until well into the 20th century. The definitions of the parts of speech include morphological, semantic, and, at least implicitly, syntactic criteria, but they suffice and so endure for centuries without much elaboration or alteration.

In fine, Alexandrian scholarship privileges textual and literary criticism and the manifold linguistic issues ancillary to such endeavors, and if grammar is not yet autonomous, it is nearly so. Language science now possesses an extensive metalanguage, linguistic levels are clearly demarcated, and the phonological and morphological parameters of linguistic inquiry are well established even if syntax still remains hidden in the dark domains of Stoic logic and/or solecisms (but see Swiggers and Wouters, 2003). The word-class system of grammar instituted by Stoic and Alexandrian language science readily transfers to the Roman world.

Linguistic Theory and Practice in Rome: Varro

Intellectual activity, along with military, political, and economic power, moves westward in the late 1st and 2nd centuries B.C. to Rome. Educated and bilingual Romans are aware of their literary and linguistic

debts to Greece, as early Latin literature abundantly attests. In 168 B.C. or so, Crates of Mallos, a Stoic philosopher, introduces Romans to the formal study of literature and linguistics. (Bits and pieces of his unconventional poetics are beginning to emerge from a papyrus roll discovered in the mid-18th century but only recently edited.) Early Roman language science, however, is decidedly Alexandrian in mode (editions of poetry, commentaries, etymological analyses, interpretations of hymns and legal documents, etc.) but also demonstrably practical and quintessentially Roman in purpose (orthography and spelling reform). Lucius Aelius Stilo (*fl.* 100 B.C.), Rome's first philologist of note, teaches both Cicero and Marcus Terentius Varro (116–27 B.C.), and the latter becomes Rome's most famous scholar.

Varro's intellectual curiosity is all-consuming and his learning vast – he authors at least 74 works – but dearest to his soul is the Latin language. Of the dozen or so major works he authors on language science, however, only six of the original 25 books, i.e., chapters, of his *magnum opus*, the *De lingua Latina*, remain. His eclectic work combines Greek and Latin linguistic thought into a distinctively Roman blend of language science. The books on etymological theory, morphological practice, and syntax are lost, but fragments suggest that Varro's syntax is Stoic, i.e., it deals with propositions. Books 5–6 on etymological practice are an enormous reservoir of cultural artifacts testifying to what Romans think about their own language, and books 8–10 on morphological theory are replete with penetrating observations on the nature of language and linguistic inquiry. Varro's accomplishments in the *De lingua Latina* are numerous: he addresses etymology from a distinctly scientific perspective; distinguishes, for the first time in ancient linguistic thought, between derivational and inflectional morphology; formulates the first embryonic declensions and conjugations in ancient language science; is the first and only grammarian in ancient times to apply abstract models to the articulation and solution of linguistic problems; so creatively adapts the Stoic analysis of the Greek verb to the Latin verb system that he becomes the only Latin grammarian prior to the Renaissance to recognize the future perfect indicative; and even includes syntax in his account of the Latin language. Such achievements arguably establish that Varro is classical antiquity's premier linguistic theoretician.

According to Varro's word-based theory (cf. Taylor, 1974 and 1996), words are of two sorts: those that vary in form, and those that do not. *Declinatio* 'morphological variation' is a linguistic universal and is likewise of two sorts: *declinatio voluntaria* is derivational morphology, and *declinatio naturalis* is inflectional morphology. Varro determines that Latin has four *partes orationis* 'parts of speech': words with case, words with tense, words with both, words with neither. How words vary inflectionally is determined by both their *figura* 'phonological form' and their *materia* 'grammatical substance,' and thus *similitudo* 'linguistic similarity' is a matter of both form and substance (but not meaning). The linguist's task is to identify *similitudo* wherever he can, and *analogia* 'proportion' is his most useful heuristic procedure. Varro utilizes four arithmetical proportions as models of inflection, which allow him to discover both declensions and conjugations. Because he ignores vowel length, his five declensions are not the same as our five, and his conjugations are only three in number; nonetheless he succeeds in identifying, perfectly in theory and almost so in practice, the declensions and conjugations of Latin, and these form the core of Latin grammar forever. Varro's status as a grammarian *par excellence* and the *vir Romanorum eruditissimus* is thus guaranteed, and it is no wonder that he is the most frequently cited source in the Roman grammatical tradition and *ergo* the first authorial figure in the history of Latin linguistics.

Early Roman Imperial Grammar and the Alexandrian Renaissance

During the first two centuries A.D., Rome attracts scholars from all over its far-flung empire who publish extensively on lexicography, orthography, and metrics, but most such texts are lost. The pace of language science accelerates, grammars assume their canonical form, and the now prominent discipline garners attention from emperors and critics alike. Grammarians like Palaemon and Probus are able to specialize on the uninflected parts of speech and the verb respectively and to become sufficiently famous that later works are spuriously attributed to them. Palaemon substitutes the interjection for the article, which Latin lacks, in the Alexandrian list of *partes orationis* and is also credited with authoring the first Roman *ars*. Meanwhile, Greek scholars like Apollonius Dyscolus (cf. Blank, 1981 and Householder, 1981), his son Herodian, and Sextus Empiricus produce influential and innovative works. Apollonian language science dominates Byzantine linguistics, and Priscian's Latin grammar (see below) is heavily dependent upon Apollonius and Herodian. The latter's works have not survived independently but were copiously quoted by later grammarians. Moreover, Apollonius is the first grammarian in ancient times, Greek or Roman, whose book-length works, or at least four of them, have been preserved more or less *in toto* and also the first

formal syntactician in Graeco–Roman linguistics. Sextus, a physician and philosopher, is a skeptical critic not only of grammar, the first of the liberal arts, but of all the arts and sciences.

Quintilian's description (*Institutio oratoria* I, 4–8) of grammatical education in 1st-century A.D. Rome is the most extensive extant Latin linguistic text of the period. Quintilian is not himself a grammarian, but his text is our best source for early imperial grammar. His organizational scheme accords nicely with that of the *ars* in subsequent centuries as well as with what little we know of Palaemon's *ars*, whose pupil he is reputed to have been. Grammarians and their students first study sounds, then word derivation, then the parts of speech, next declension and conjugation, and finally the virtues and vices of speech, particularly barbarisms and solecisms. The tripartite arrangement of the later monumental *artes* – phonology, morphology, *vitia virtutesque orationis* – is therefore present, at least implicitly, in Quintilian's account. The study of phonology is important for reading aloud (the norm in classical antiquity), spelling, and scanning poetry, and the stylistic component presupposes at least some normative grammar. The largest section in Quintilian's educational schema is that on morphology, and it emphasizes the parts of speech, declined and conjugated forms in particular, although Quintilian nowhere classifies nouns and verbs into particular declensions or conjugations and presumably does not know them. Ambiguity interests him, and he adduces (6.1) and discusses at length four criteria for resolving ambiguities and other doubtful grammatical issues: reason (analogy or etymology), antiquity, authority, usage. He criticizes excessive reliance on any one criterion, however, and inveighs mightily against prescriptive analogy and conjectural etymology. Examples are ubiquitous throughout Quintilian's entire account of 1st-century A.D. grammatical education, and they provide fascinating glimpses into the many linguistic questions with which Roman grammarians and their students were grappling at the time. What the Romans do best, however, is to systematize and organize, and as Quintilian's sketch and subsequent *artes* suggest, that is what it appears they do most of all for language study in the early empire.

Apollonius Dyscolus is a rationalist and an analogist: linguistic problems have reasonable solutions, and similar problems have analogous solutions. Language is by nature logical, orderly, and rule governed; any and all deviations from linguistic logic, order, and rule are explicable by reason and analogy; and grammatical analysis is therefore principled behavior designed to discover rules and to explain exceptions. Apollonius assumes an underlying structure for all levels of language. So there is an order to the letters of the alphabet, to the parts of speech, to the cases, and to the sentence. Letters combine into syllables, syllables into words, and words into sentences, but constraints obtain; therefore none of these processes is random. Change (*pathos*) affects each level, however, and Apollonius analyzes change as addition, deletion, substitution, and transposition, i.e., the four transformations or the *quadripartita ratio*. Just as words are subject to *pathos*, i.e., are misspelled, and are corrected by the theory of spelling, so too sentences may consist of improperly combined *noeta* 'meanings' (Apollonius is also a mentalist) and are to be corrected by syntactic theory. He decomposes complex syntactic structures with subordination into synonymous but coordinate simple structures and analyzes elliptical constructions on the basis of complete ones. Apollonius's insistence on an underlying structure to phonology, morphology, syntax, and semantics is remarkably forward-looking and allows him to stress *katallēlotēs* 'grammaticality' and to seek such structures where they are not overtly apparent. Sextus Empiricus could not disagree more. For him, a science of grammar is simply not possible, and he therefore debunks Stoic and Alexandrian grammatical doctrines alike with impartial glee. In so doing, however, Sextus provides precious information, albeit negatively expressed, about both Stoic and Alexandrian linguistic thought. He also proves himself a keen observer of both diachronic change and synchronic variation. He reports quite accurately that *oi*, *ei*, *ou*, and *ai* are no longer diphthongs, that *zeta* is now simply [z], and that the aspirated stops *phi*, *theta*, and *chi* have become continuants. He also stresses the role of style, register, or idiolect and how it varies from speaker to speaker or from speech act to speech act. Of course, Sextus adduces such observations in order to argue, *pace* his predecessors, that neither analogy nor usage, separately or in tandem, can establish correctness in speech. We know little about either Apollonius (e.g., why he was called Dyscolus 'ill tempered') or Sextus (e.g., where he lived), but together they constitute the last chapter in the history of ancient Greek linguistics.

The Roman *Ars Grammatica*

In late antiquity, grammar is the undisputed queen of the sciences: the sheer quantity of grammatical texts dwarfs that of the preceding centuries taken collectively; numerous grammarians are represented in the corpus of extant texts; many others who are otherwise unknown are mentioned in those texts; and grammarians everywhere enjoy a status in society that guarantees them respect and remuneration.

Unfortunately, few texts have been edited properly, and we must therefore depend for the most part upon Keil's eight mammoth but outdated volumes (1857–1880). Worse, prosopography is often chaotic, footnoting either casual or conspicuous by absence, and plagiarism rampant. Extant *artes* range from textbooks to reference grammars, their authors include amateurs as well as professionals, and even a new genre, the grammatical commentary, emerges. Thus, contents vary widely from favorite themes to areas of expertise, methods comprise the purely formal and the heavily semantic (sometimes both in the same text), and elaborate taxonomies abound. Despite such diversity these *artes* nonetheless manifest an apparent uniformity that obfuscates their authors' occasional forays into independent thought. Therefore determining with precision the historical course of progress, dependence, influence, and innovation is virtually impossible, but the wealth of information in these copious *artes* is undeniably vast. Phonology, spelling, orthography, metrics, the *partes orationis* and their accidence, declensions, conjugations, comparison, *vitia virtutesque orationis*, even syntax, and countless other topics all receive their due and more, and grammarians ruthlessly mine both pagan and Christian texts for relevant literary examples.

Sacerdos (3rd century A.D.) authors the first extant *ars*, but it is in the next century that grammar proliferates and rises to prominence. Charisius regularly exercises his own judgment as he reviews and critiques Roman grammatical literature; Diomedes can be unduly influenced by Greek sources one moment but quite independent, even radical, the next; and Donatus, the teacher of St Jerome and the most famous and influential contemporary grammarian, produces two classics, his *Ars major* and *Ars minor*. The latter is a series of questions and answers concentrating exclusively on the parts of speech and testifying to the preeminent place of morphology in Latin grammar, whereas St Augustine reprises much of Stoic linguistics in his *De dialectica*. Contrastive linguistics looms larger as both the Roman empire and grammar become bilingual, a fact much in evidence in the grammatical works of Marius Victorinus, Macrobius, and Dositheus. The 5th century features equally frenetic grammatical activity. Consentius and Phocas limit their *artes* to the noun and verb: both take a deductive approach to Latin grammar, but the former emphasizes definitions and explanations in the manner of schoolbooks while the latter produces a *regula*-type grammar heavy on rules, paradigms, and examples. Servius, Cledonius, and Pompeius inaugurate the new genre of grammatical literature by commenting on the texts of Donatus. Martianus Capella's bizarre fantasy on the marriage of Mercury and Philology ranks the *ars grammatica* as the first of the *artes liberales* just as Varro's *Disciplinae* had done more than a half-millennium previously.

Priscian's *Institutiones grammaticae* (5th–6th century A.D.) constitutes the stunning and surprising culmination to the history of Graeco–Roman language science. Priscian is a data-oriented grammarian who devotes his first 16 books to morphology; examples and literary quotations by the thousands enhance some of the most extensive morphological analyses in the entire history of linguistics. (His abridged treatise on the noun, pronoun, and verb becomes a pedagogical classic.) Semantics reigns supreme in his linguistic theory, however, for Priscian is heavily dependent upon Apollonius Dyscolus, as befits a grammarian writing in Constantinople. Priscian devotes books 17 and 18 to syntax, the first such study in all of Roman language science. He relies on Apollonius for theory, form, content, and methodology, and thus reason, analogy, order, and, obviously, semantics figure prominently everywhere. He cites Apollonius repeatedly and even recasts in Latin Apollonius's famous analogy between spelling and syntax. Like his Greek predecessor, Priscian decomposes complex structures into simpler ones and analyzes ellipses on the basis of complete constructions. Especially noteworthy, are Priscian's analyses of the ablative absolute, gapping, the passive transformation, and impersonal verbs. Priscian's work is so significant that it is transmitted in more than a thousand manuscripts, and his syntax so striking that books 1–16 and books 17–18 are often separately entitled *Priscianus major* and *Priscianus minor*, respectively. Priscian's supreme achievements in morphology and syntax are difficult to assess in detail, for even now we still "have no extensive study of him nor even a satisfactory philological edition of his work" (Hovdhaugen, 1982: 105); nonetheless his *magnum opus* stands as the consummate swan song to ancient language study.

Conclusion

Western intellectual history would not be the same without the contributions of classical antiquity's language scientists, for individually and collectively the grammarians of Greece and Rome lay the foundations and chart the course for the formal study of language in the future. Their claims on originality are considerable; the four transformations, parts of speech, grammatical terms by the score, the word-class system, word-and-paradigm grammar, sign and referent, and dozens of other linguistic matters first articulated in Greece or Rome are still with us

today. Plato and Aristotle begin the lengthy process of identifying the fundamental constituents of language, Stoic logic remains *au courant*, the *Techne*'s taxonomic and terminological influence is indisputable, Varro's revised declensions and conjugations are the permanent heart and soul of Latin grammar the world over, Donatus's *artes* are centerpieces of grammatical literature and educational curricula, and Priscian's syntactic analyses have found their way into modern textbooks. The history of Graeco–Roman language science is not always as well documented as we would like, but what is extant not only testifies to one of the longest-lasting intellectual legacies in the Western world but also continues to inspire and inform its modern practitioners.

Introduction

The evaluation of speech and language is one of the most important tasks of speech-language pathologists and professionals from a variety of disciplines and backgrounds (neuropsychologists, physicians, nurses, etc.). The assessment session is often the first contact with clients and also constitutes the starting point of all clinical interventions. Because of the absence of biological markers or simple assessment methods, the early detection or diagnosis of speech and language problems remains dependent on various indirect assessments (i.e., speech or language functioning must be inferred from the client performance in various tasks devised to explore the different areas of this functioning) performed to identify specific impairments and eliminate other possible causes.

There are various purposes to conduct speech-language assessments. The main goal of screening is to determine whether a client has a problem or not. The output of this type of assessment is a 'pass' or 'fail' result, based on an established criterion that could lead to a more extensive or a follow-up assessment. Diagnosis and differential diagnosis assessments are usually performed to label the communication problem and/or to differentiate it from other disorders in which similar characteristics are usually reported.

Another important purpose to evaluation is to provide clinicians with a detailed description of the client's baseline level of functioning in all areas of communication in order to identify affected and preserved components, to plan for treatment, to establish treatment effectiveness, or to track progress over time through periodic re-evaluations. These types of assessment require the clinician to consider all aspects of communication, including the different areas of speech (e.g., articulation, voice, resonance) and language (e.g., lexical access, comprehension, written spelling), but also important related abilities and components such as pragmatics, cognitive functions (e.g., attention, memory, visual perception), emotions, awareness of deficits, etc. The selection of evaluation tools is also conditioned by the specific objectives of assessments. Screening for a speech or language disorder is usually performed with standardized screening measures whereas standardized norm-referenced tests are used for diagnosis and differential diagnosis assessments as well as for clinical treatment purposes (baseline, effectiveness, progress).

Reference Models for the Assessment of Speech and Language Impairment

The choice of a particular method of assessment, the selection of evaluation tools as well as the interpretation of results, is highly dependent not only on the clinician's own conception of speech and language functioning but also on the reference to a clinicopathological or cognitive model of assessment.

In the clinicopathological model, speech and language problems are considered as essential characteristics of clinical syndromes. These clinical syndromes are organized and classified according to neurological-neuropathological characteristics (e.g., deterioration of cortical tissue in a specific brain area) and according to semiology (e.g., sensitive and motor deficits, visuospatial deficits, language deficits, etc.). For the purpose of assessment, the emphasis is put on the precise identification of the diagnostic label that best corresponds to the observed deficits as well as to the identification of the possible etiology. For example, within this model, the general assessment process of an aphasic person essentially consists of (1) gathering case history data (e.g., cerebrovascular accident in the left frontal area), (2) administrating a specific test battery (e.g., the Boston Diagnostic Aphasia Examination [BDAE]; Goodglass *et al.*, 2000), (3) confronting the results and description of behavior (e.g., impaired fluency, impaired articulatory agility, relatively good auditory comprehension, agrammatism) with the classification of neurogenic acquired deficits of language, and (4) specifying the precise aphasic label (Broca's aphasia) that best fits these characteristics. If screening or labeling is the main goal of the assessment, the clinicopathological model is probably the best option. It is, however, certainly not so if the purpose of the evaluation is to localize the functional origin of deficits or to guide clinical practice. Knowing that a person presents with a Broca's aphasia may not be much help in identifying the specific components of language that are totally or partially affected or preserved. It also does not tell the clinician what intervention goals are appropriate, what treatment approaches will succeed best.

Instead of resorting to a medical assessment model, clinicians may use cognitive neuropsychological models, directly derived from information-processing theories, to evaluate language. In these models, cognitive functions, including language, are sustained by specialized interconnected processing components,

represented in functional architecture models. For example, as shown on Figure 1, the ability to orally produce a word in picture naming is conceived as a staged process in which the activation flow is initiated in a conceptual-semantic component and ends with the execution of articulation mechanisms.

An assessment process based on cognitive neuropsychological models consists in the localization of the impaired and preserved processing components for each language modality. This localization is performed through the administration of specific tasks or test batteries (e.g., Psycholinguistic Assessments of Language Processing in Aphasia [PALPA]; Kay *et al.*, 1992) aiming at the evaluation of each component and route of the model. For example, the evaluation of naming abilities in an aphasic person could be performed by the administration of tasks exploring the conceptual-semantic (e.g., semantic questionnaire), phonological output lexicon (e.g., picture-naming task controlled for frequency, familiarity, etc), and phonological output buffer (e.g., repetition of words and nonwords controlled for length) components. Important information regarding the level of impairments also arises from error analysis. With the same example, an anomic behavior could arise from distinct underlying deficits (e.g., in the activation of conceptual-semantic representations or in retrieving phonological forms of words in the output lexicon), leading to distinct types of errors (e.g., semantic substitutions, phonemic errors). The complete cognitive assessment process should allow the clinician to understand the client's deficits (i.e., surface manifestations, underlying origins, affected components) as well as to identify the strengths and weaknesses in his communication abilities. When recommended, the treatment may focus on the impaired levels of processing (i.e., function restoration) or on alternative processing routes (i.e., function reorganization) that will allow the client to communicate successfully.

Figure 1 Schematic depiction of the cognitive neuropsychological model of spoken picture naming.

Classical Tests for the Assessment of Aphasia

Aphasia is the most common disorder of communication resulting from brain damage (i.e., stroke, brain tumor, head trauma, infections). This affection mainly involves language problems of production and comprehension as well as disturbances in reading and spelling.

Bedside and Screening Tests

The patient's symptoms change rapidly during the first days and weeks following the brain damage. Moreover, patients are often too ill to complete an exhaustive aphasia examination and bedside or screening instruments may be useful to advise relatives and health care professionals about the global communication profile and the best means to communicate in functional situations. These instruments are also useful to help clinicians to determine the necessity of performing a more thorough and extensive assessment of language or to establish the priority of patients on a waiting list. In addition to actual screening tests (e.g., Aphasia Screening Test; Reitan, 1991; for an extensive list see Murray and Chapey, 2001 and Spreen and Risser, 2003), clinicians also may administer shortened versions of comprehensive tests of aphasia (e.g., short form of the Token Test; Spellacy and Spreen, 1969; for an extensive list see Murray and Chapey, 2001). As pointed out by Spreen and Risser (2003), although bedside and screening tests may be used to identify language impairments in moderate and severe aphasics (language is obviously affected, even in simple and natural communication situations), they are inappropriate or of little use to distinguish the responses of individuals with mild deficits from those with normal language skills.

Comprehensive Examinations and Aphasia Batteries

As compared to bedside and screening tests, the main purpose of comprehensive examinations of aphasia is to provide an extensive description of language skills through the administration of tests designed to explore the different areas of language (i.e., spontaneous speech, naming, oral expression, auditory and written comprehension, repetition, reading, and writing). According to the reference model of assessment, the

output of a comprehensive examination may consist in the identification of a particular diagnostic of aphasia with the description of severity of deficits in each language area (clinicopathological approach), or in the localization of specific impairments affecting functional processing components of language skills (cognitive neuropsychological approach).

There are several classical comprehensive examinations and aphasia batteries. The most widely used in clinical and research settings in English are BDAE (Goodglass *et al.*, 2000), the Western Aphasia Battery (Kertesz, 1982), and the Aphasia Diagnostic Profiles (Helm-Estabrooks, 1992). All these standardized test batteries comprise different subtests (e.g., BDAE has 27 subtests) that assess all the dimensions of language in order to diagnose and classify aphasic syndromes according to clinical localization-based classifications (i.e., Broca's, Wernicke's aphasia, etc.). For a complete description and a critical review of these instruments, and others not reported here, see Spreen and Strauss (1998), Murray and Chapey (2001), and Spreen and Risser (2003). PALPA (Kay *et al.*, 1992) is a comprehensive test battery directly derived from the cognitive neuropsychology approach of assessment. This aphasia battery, commonly used in the United Kingdom, consists in a set of resource materials comprising 60 rigorously controlled tests that enable the user to select tasks "that can be tailored to the investigation of an individual patient's impaired and intact abilities." The scoring and analysis of errors give the clinician a detailed profile of language abilities, including reading and written spelling, which can be interpreted within current cognitive models of language. As compared to classical batteries of aphasia, the versatile and flexible nature of PALPA is, however, lessened by the lack of standardization and validity/reliability measures.

Tests for the Assessment of Specific Aspects of Language

Specific aspects of language behavior can also be assessed through the administration of several tests. These are often used to complete aphasia batteries but some of them also are used as screening tests. Clinicians may select these tests according to the different aspects of language they want to explore in depth, but also according to the underlying theoretical model of assessment. For example, comprehension may be tested through the administration of specific tests aiming at the discrimination of phonemic sounds (Phoneme Discrimination Test; Benton *et al.*, 1994), semantics (Pyramids and Palm Trees Test; Howard and Patterson, 1992), sentence length and syntactic complexity (Auditory Comprehension Test for Sentences; Shewan, 1979), commands (Token Test; De Renzi and Vignolo, 1962), or narrative discourse (Discourse Comprehension Test; Brookshire and Nichols, 1993). Other tests are available for measuring verbal expression, spoken and written naming, verbal fluency, reading, writing, gestural abilities, etc. An extensive list of specific language function tests can be found in Spreen and Strauss (1998), Murray and Chapey (2001), and Spreen and Risser (2003).

The Assessment of Functional Communication

Traditional tests provide useful information on linguistic abilities and language impairments in aphasia. However, performance on these tests does not necessarily predict how a person will communicate in more naturalistic settings and everyday life. Instead of focusing on the importance and the nature of deficits, the functional communication approach of assessment aims at the impact of these deficits on the person's activities and participation in society. Functional communication skills may be assessed with specific structured tests or by rating scales and inventories of communication profiles. Structured tests such as Communication Activities of Daily Living 2 (Holland *et al.*, 1999) and the Amsterdam–Nijmegen Everyday Language Test (Blomert *et al.*, 1994) have been devised to explore functional communication skills using role-play in daily life activities (shopping, dealing with a receptionist, etc.) and have shown themselves to be useful to track progress over time. However, while they are certainly more ecological than comprehensive examinations and tests for specific aspects of language, structured tests of functional communication do not necessarily give reliable views of the communication skills of a person in real-life situations. In this respect, rating scales and inventories of communication profiles are closer to functional situations. For example, the Functional Assessment of Communication Skills for Adults (Frattali *et al.*, 1995) is a rating protocol of 43 items, on a seven-point scale, based on the observations made by the speech-language pathologist or other significant person in the following four domains: social communication (e.g., 'refers to familiar people by name'); communication of basic needs (e.g., 'makes needs to eat'; reading, writing, and number concepts (e.g., 'writes messages'); and daily planning (e.g., 'tells time'). For a more extensive description of these functional communication tools, and others not described here, see Murray and Chapey (2001) and Spreen and Risser (2003).

Classical Tests for the Assessment of Speech and Language Impairment in Children

The assessment of language and communication in children can take place from infancy through

adolescence, when cognitive abilities are developing. Therefore, the language assessment process must not only inform on current specific abilities, but has also to capture changes over time in the level, sequence, and rate of acquisition. The interrelationship between language and other cognitive and social skills is also of primary importance. As a part of a larger process, usually performed by different professionals, the evaluation of language in children should be completed by an assessment of nonverbal communication, play and social skills, perception, attention and memory, behavior, etc. Moreover, because of the major influence it has on child development, the evaluation also has to consider the familial and social environment, especially with respect to adult–child interaction. The different components (e.g., sensitivity, promptness) as well as the context (e.g., physical settings, types of play, activities) in which this interaction takes place should be analyzed through specific assessment tools or through direct observation.

The assessment of preschool children (children aged 2 to 5 years) and school-age children (5 to 10 or 12 years) is usually based upon a combination of parent interviews, standardized tests, criterion-referenced instruments, developmental scales, and observations. All these tools and methods aim to explore both receptive and expressive language abilities in semantics, morphology, syntax, phonology, and pragmatics. Collecting a communication sample is also a frequently used method to analyze communication in terms of sentence length, intelligibility of speech, vocabulary, and conversational strengths and weaknesses. Similarly to tests for aphasia, preschool and school-age tests can be divided into two major categories: screening and diagnostic tests. The purpose of screening tests is to determine if the child's communication should be explored more extensively for the presence of a possible impairment. On the other hand, the main purposes of diagnostic tests is to establish the presence or absence of a deficit in one or more areas of language, to identify a possible difference in language development, to determine the child's eligibility for clinical services, and to identify the targets for intervention. These instruments are devised to assess language development by reference to the parameters of the normal range.

Screening Tests

Screening tests are usually inexpensive and require minimal time for administration and interpretation of results. Many norm-referenced standardized instruments may be used to establish the child's general level of expressive and receptive language functioning as well as other areas of functioning. For example, the Denver Developmental Screening Test II (Frankenburg *et al.*, 1990), a standardized screening battery for children from birth to age 6, is designed to test the child's abilities in the following four sectors: personal-social, fine motor, gross motor, and language (including expressive-receptive vocabulary). Screening tests may also consist in large batteries exploring language and cognitive functions through tasks of general verbal and nonverbal intellectual abilities. For example, the Wechsler Intelligence Scale for Children IV (Wechsler, 2004) is the most widely used measure of verbal and nonverbal intelligence in individuals from age 6 years 0 months to 16 years 11 months. As a screening tool, this battery consists in 16 subtests of verbal comprehension, perceptual reasoning, working memory, and processing speed skills.

For school-age children, some large screening batteries specifically concern academic achievement. That is, for example, the case with the Peabody Individual Achievement Test – Revised (PIAT-R; Markwardt, 1998), which provides a screening measure of achievement in the areas of mathematics, reading recognition and comprehension, spelling, and general information. However, most of the tasks of these large screening batteries are multifactorial and are therefore not appropriate to assess specific language or cognitive processes. For this purpose, clinicians may select among various specific screening tests for preschool and school-age children that focus only on language. Most of these instruments are designed to explore the different language components. That is the case, for example, with the Fluharty Preschool Speech and Language Screening Test II (Fluharty, 2001), which explores articulation, expressive and receptive vocabulary, and composite language in children from 2 to 6 years old. An exhaustive list of norm-referenced standardized screening tests of language can be found in Paul (2001).

Comprehensive Examinations and Batteries

As for screening, some diagnostic tools are designed to explore language skills as well as other aspects of development. That is the case, for example, with the Communication and Symbolic Behavior Scales Developmental Profile (Wetherby and Prizant, 1998), which includes tasks exploring expressive and receptive language, symbolic play, and nonverbal communication in children from 6 to 24 months old. Another example is the Rossetti Infant-Toddler Language Scale (Rossetti, 1990), which is used to assess attachment, play, gestures, and pragmatics, as well as language comprehension and expression in children from birth to 3 years old. There are also several

standardized comprehensive batteries of language processing that comprise tests exploring exclusively some or all of the language areas. That is the case, for example, with the Preschool Language Scale 4 (Zimmerman *et al.*, 2002), which is used to identify specific strengths and weaknesses in receptive and expressive language skills in children from birth to 6 years 11 months. The Clinical Evaluation of Language Fundamentals 4 (Semel *et al.*, 2003) is a multidimensional battery that can be used in individuals between the ages of 5 and 21 years to explore semantics, expressive and receptive language, and syntax, as well as working memory. The Comprehensive Assessment of Spoken Language (Carrow-Woolfolk, 1999), designed for children from age 3 to 21, is another comprehensive battery of language skills, comprising 15 tests that provide an assessment of expressive and receptive skills in four language categories: lexical/semantic, syntactic, supralinguistic, and pragmatics. An extensive list of available comprehensive examinations and batteries of language for children can be found in McCauley (2001), Paul (2001), Mattis and Luck (2002), and Haynes and Pindzola (2003).

Tests for Specific Aspects of Language

Different components of language can be affected with more or less intensity in children according to the origin of developmental disorders. Therefore, the in-depth assessment of language and communication disorders in children is a critical component in the clinical process. Core tests can be used to evaluate each of the language areas in order to identify specific impairments, establish baselines, and identify precise therapeutic and intervention goals. For example, there are several core tests and instruments for the evaluation of word retrieval (e.g., naming and verbal fluency tests), phonology (e.g., word and nonword repetition tests), receptive and expressive vocabulary (e.g., word definition tests), receptive and expressive syntax and morphology (e.g., sentence-to-picture matching tests), and pragmatic skills (e.g., narrative production, story comprehension tests).

A combination of different tests, each focusing on specific language components, may also be used to establish such a language and communication profile. For example, to assess vocabulary, clinicians may select the following standardized norm-referenced specific tests: the Expressive One-Word Picture Vocabulary Test Revised (Gardner, 2000), to exclusively explore expressive vocabulary in individuals ages 2 years 0 months through 18 years 11 months; or the Peabody Picture Vocabulary Test (Dunn and Dunn, 1997), to exclusively explore receptive vocabulary in individuals from age 2 years 6 months to adult. A more complete description of available diagnostic tests adapted to preschool and school-age children can be found in McCauley (2001), Paul (2001), Mattis and Luck (2002), and Haynes and Pindzola (2003).

The Assessment of Reading and Writing

The relationship between language acquisition and academic achievement is well established. Developmental disorders of language in preschool children are frequently associated with later difficulties in learning to read and write. The most common referral for a speech-language pathology assessment concerns school-age children who encounter problems in progressing beyond the developing language phase and present with difficulties in learning and acquiring communicative and academic skills. As for other populations, but especially at this stage of development, a significant difficulty in assessing school-age children arises because of important comorbidity between language and learning disorders and other cognitive and clinical pathological profiles, such as attention deficit/hyperactivity or executive function disorders. Therefore, the assessment process should include specific tests of language and communication but also instruments designed for exploring other cognitive functions, such as attention, working memory, and executive functions. In addition to formal tests, another important source of information also comes from structured interviews of the child himself, his parents and his teacher. With respect to language, phonological processing deficits are considered as an underlying cause of dyslexia and also play a role in developmental disorders of spelling. For example, dyslexic children often show problems with word and nonword repetition tasks, phonological awareness tasks (e.g., word and nonword segmentation tasks, phoneme manipulation, etc.), and working memory tasks for verbal material (i.e., word or digit span tasks). The semantic processing is another cognitive area highly related to reading and writing. School-age children usually learn new words through reading and writing. Those who encounter problems in reading and writing often present with poor vocabulary as well as with difficulty in word association and comprehension. Therefore, the assessment procedure for written language problems should be part of a more exhaustive evaluation of language and cognition. It should also include a close control of psycholinguistic parameters (e.g., orthographic regularity, lexical frequency) that are known to play an important role in written and spoken word recognition, reading comprehension, phoneme–grapheme

conversion, decoding, etc. However, very few standardized assessment tools fulfill these conditions. As an exception, French-speaking clinicians may use the Batterie d'Évaluation du Langage Écrit et de Ses Troubles (Mousty *et al.*, 1994), a written-language-testing battery based on current models of reading and writing, to assess children between the ages of 7 and 12 years. In addition to experimental tasks, one can resort to standardized achievement or specific tests of reading and writing skills. Among the most used of achievement tests are PIAT-R (Markwardt, 1998), which comprises subtests of reading comprehension, reading recognition, and spelling, and the Wide Range Achievement Test (Wilkinson, 1993), a brief test measuring reading recognition, spelling, and arithmetic computation. For a description of specific clinical tests of reading and writing, see Spreen and Strauss (1998) and Bailet (2001).

Classical Tests for the Assessment of Speech and Language Impairment in Special Populations

Referral for speech-language assessment not only concerns aphasia and developmental deficits of language but also involves individuals of different age groups presenting with various language and communication problems. In children and adolescents, these references include language deficits in pervasive developmental disorders (e.g., autism, Asperger's disorder), mental retardation, attention deficit/hyperactivity disorder, specific language impairment, sensory deficits (hearing loss, blindness), acquired disorders (e.g., traumatic brain injury), stuttering, etc. In adults, referral for a speech-language evaluation may be required for language and communication deficits following right hemisphere damage, traumatic brain injury, Alzheimer's disease and other forms of dementia (e.g., primary progressive aphasia, semantic dementia), stuttering and other fluency problems, etc.

In children, adolescents, and adults, clinical assessments may also concern such speech problems as dysarthria, following a stroke and neurodegenerative illnesses or accompanying cerebral palsy, acquired or developmental apraxia of speech, etc. In addition to the conventional evaluation of basic language (or speech) skills, the assessment procedure in all these special populations involves specific aspects and particularities of speech and language. For example, because of the absence of biological markers or simple diagnosis methods, the early detection of dementia often depends on various assessment tools, including language and cognitive tests performed to exclude other possible disease processes or identify specific forms of a given disease. In that particular domain, the assessment of speech and language usually includes tests allowing for differential diagnosis. For example, tests that specifically tap either semantic processing or written spelling can contribute to differentiating common disease processes in the elderly population. Semantic deficits are prominent characteristics of individuals diagnosed with Alzheimer's disease and these individuals usually differ from patients diagnosed with vascular dementia or frontotemporal dementia because of the presence of surface dysgraphia, a specific spelling disorder.

It is obviously not possible to exhaustively describe here the various tests adapted to special populations. The reader will find a more complete description of such tests in McCauley (2001), Paul (2001), Haynes and Pindzola (2003), and Spreen and Risser (2003).

Conclusion

Language production and comprehension are complex cognitive skills that should not be considered in isolation in assessment procedures. The interrelation between language and other cognitive functions has to be captured, particularly with respect to the possible influence of attention, working memory, and executive functions on linguistic abilities. If possible, clinicians should always select valid and reliable norm-referenced tests to assess language and communication. Resorting to theoretical models of language functioning also appears of primary importance and may sometimes condition the utilization of experimental, well-controlled, assessment tasks. A comprehensive assessment of language and communication is more than just an evaluation of specific skills in terms of preservation or impairment of processing components and surface structures. The scope of assessment should be widened in order to provide information about physical, social, and emotional contexts of communication, cultural differences, and economic factors. The combination of these data, obtained through assessment tools and direct observations, should then allow the clinician to establish a complete portrait of functional communication abilities.

Classification of Languages

Classification of Languages

This article describes the principles underlying the classification of languages in this encyclopedia. Classification may be based on genetics, diffusion, lexicostatistics, or other relationships. A map (Figure 1) showing locations of major language groupings worldwide is provided.

Genetic Classification

Both professional linguists and general readers find a genetic classification the most satisfying way to group languages. This approach is one in which languages are classified into families on the basis of descent from a common ancestor. A good example is the Indo-European family of languages, which includes most of the languages of Europe, Iran, Afghanistan, and the northern part of South Asia. These languages can be shown to descend from a common ancestor, a common protolanguage. There are no records of the ancestral language, but it can be reconstructed from records of daughter languages such as Sanskrit, Ancient Greek, and Latin by using what is known as the 'comparative method'. Consider the following words for 'father': Sanskrit *pitár*, Greek *paté:r*, and Latin *pater*. It is possible to align the initial *p*s, the medial *t*s, and the final *r*s and reconstruct a root with the consonants *p-t-r* (the vowels require a little further examination). English is also a related language, so the word *father* should show the same consonants, but in fact the expected *p* shows as an *f* and the *t* shows up as a *th* (representing a voiced dental fricative). However, a consideration of further words shows that the *f/p* correspondence also appears in many other words, such as English *foot* against Sanskrit *pád-*, Greek *pod-*, and Latin *ped-*, and the *th/t* correspondence also shows up in other words, such as English *mother* against Sanskrit *ma:tá:r*, Greek *má:te:r*, and Latin *ma:ter*. We still reconstruct *p-t-k* and conclude that English has systematically changed the original stop consonants into fricatives. In fact, all the Germanic languages have done so.

Inflections as well as roots can be reconstructed. A common genitive ending in *-s* can be seen in Greek *pod-ós*, Latin *ped-is*, and English *foot's*. Proceeding in this way, we can reconstruct a good deal of the protolanguage and we can demonstrate that these languages and a score or so others are related as members of one family, which we call Indo-European.

A language family can be represented by a tree diagram, with the branches representing subgroups. Subgroups are characterized by shared innovations, which sets them apart from other languages in the family. The Germanic branch of Indo-European (English, German, Dutch, etc.) is characterized by various consonant shifts such as $p \rightarrow f$ and $t \rightarrow th$, as just mentioned, and by a past tense marked by a dental (or alveolar) stop, as in English *answered* or German *antwortete*. Other branches of Indo-European that can be reconstructed include Armenian, Anatolian, Celtic, Tocharian, and Italic. The Italic branch contained languages located in Italy, such as Oscan, Umbrian, and Latin. Latin was spread by conquest from Rome to a large area around the Mediterranean. It is no longer a spoken language, but it survives through its daughters, namely, French, Portuguese, Spanish, Italian, and Romanian, to mention only national languages. These languages, collectively called the Romance languages, form a sub-branch of the Italic branch of the Indo-European family. In this instance, we have records of Latin, which serves as a check on what we might reconstruct as proto-Romance. All of the Indo-European languages treated in this encyclopedia are included in the alphabetic list of families and other large groupings in the last section of this article ('Status of the Groupings Used in the Classification').

It is common in studying languages to find among them resemblances that are insufficient for the reconstruction of a protolanguage. This can be because there are insufficient data or because the languages have diverged so far that only a little evidence remains of their genetic affiliation. Where there is insufficient evidence for establishing a family or grouping families into a wider family, so that they become branches of the larger family, we can describe the languages in question as belonging to a particular stock. There can be degrees of resemblance among languages. If languages are grouped into stocks on the basis of sharing 10–20% of vocabulary, and some stocks are found to share between 5 and 10%, then these stocks can be said to belong to the one phylum.

Diffusion

In the ideal case, a number of innovations will coincide, as with the Germanic innovations mentioned previously, and a branch can be added to a tree diagram. However, all innovations, whether they

Figure 1 Locations of the major language groupings of the world, excluding the large-scale expansion of European languages such as English and Spanish over the past 500 years. The approximate locations of major concentrations are shown. In the Americas, there are many families, often with discontinuous and interlocking distributions, so the labels, indicated by name, are very approximately located.

are new pronunciations, new affixes, new words, or new constructions, must start at a particular location and then spread, and different innovations can have different starting points, and the spreads can overlap. This can happen within a particular language or between languages in contact, with the result that linguists cannot always present a neat, noncontroversial tree diagram.

The diffusion of language features can be massive and widespread. Vocabulary can be borrowed from one language to another. 'Borrow' is the conventional term for the adoption of language features from another language, but no paying back is implied. Words to do with culture are most easily borrowed. English, for instance, has borrowed almost the entire learned stratum of its lexicon from French, Latin, and Greek. Similarly, Thai, Lao, and Khmer (Cambodian) have borrowed their learned stratum from Pali, a language of the Indo-Aryan branch of Indo-European. Pali is the language of Buddhism. In areas where Islam is found, languages exhibit various degrees of borrowing from Arabic. Common vocabulary is not immune from borrowing. English, for example, has borrowed *very* from French, and it has borrowed some hundreds of fairly basic words from Old Norse, including the pronominal forms *they*, *their*, and *them*. The standard tree diagram shows English as part of the West Germanic sub-branch of Germanic and Old Norse (ancestral to the modern Scandinavian languages), as representing North Germanic, but it is more realistic to think of English as a mixture, predominantly West Germanic, but with an admixture of North Germanic. And there is also the learned stratum of vocabulary already mentioned.

Though grammatical forms, particularly bound forms such as plural markers or past tense markers, are not normally borrowed, grammatical structure or patterns are relatively diffusible. It is interesting to note that most of the languages of South Asia have subject-object-verb (SOV) word order even though they belong to different language families: the Indo-Aryan branch of Indo-European, Dravidian, and the Munda branch of Austro-Asiatic. Burushaski, a language isolate spoken in northern Pakistan, is also SOV. In China, and in Laos, Thailand, and Vietnam to the south, a number of genetically diverse languages have assimilated to Chinese in having monosyllabic roots and tones. When languages converge in this way, we have a *Sprachbund* (German for 'language union'), or linguistic area. If languages were classified typologically, then various languages of different genetic provenience would be classified together because of diffusion. Vietnamese is a good example. Historically, it belongs to the Mon-Khmer branch of Austro-Asiatic, but it has been so influenced by Chinese that not only has it adopted numerous Chinese words, but it has also reduced its own roots to conform to Chinese patterns and it has developed tones as in Chinese. Word order is subject-verb-object, as in Chinese.

Lexicostatistics

Linguists are not always in a position to reconstruct the relationship between languages as has been done in the case of Indo-European. Where linguists have been confronted with a number of languages that have not been studied in detail, a common situation outside Europe over the past century, they have resorted to lexicostatistics. The method is very simple. The percentages of common roots are counted using a list of 'basic' words. The theory is that basic vocabulary is resistant to borrowing, so that the percentage will give a guide to how closely languages are related. Although it is true that everyday words are less easily borrowed compared to words to do with culture (in the broadest sense), the difference is one of degree. One of the 200-word lists of basic vocabulary that has been used contains the numerals 'one', 'two', 'three', 'four', and 'five', but these can be borrowed, as in the case of the Tai languages, which have borrowed them from Chinese. The same list also contains 'animal', 'lake', and 'mountain', all of which are borrowings in English, ultimately from Latin. The problem of distinguishing roots that have been borrowed as opposed to those that have been inherited from a protolanguage is even greater when dealing with languages for which no detailed descriptions are available. Nevertheless, lexicostatistics has been widely used in the classification of the languages of various areas, including Africa, the Americas, Australia, and New Guinea. Lexicostatistics does give a good guide to the degree of similarity between languages, and on the basis of the percentages obtained it is possible to draw a hierarchical tree diagram and classify languages in terms of phylum, stock, family, branch, sub-branch, language, and dialect. However, there is no guarantee that such a tree diagram reflects the successive breaking up of protolanguages, and the terms *family*, *branch*, and *sub-branch* do not have the same meaning as these terms do when based on the comparative method.

Greenberg classified the languages of Africa and the Americas using a form of lexicostatistics. Although his classification of African languages is widely accepted and in general use, his classification of the languages of the Americas is rejected by most scholars. In this classification, all of the languages of the Americas are united in one vast Amerind family, except for Na Dene (mainly in northwestern part of

North America) and Eskimo-Aleut in the Arctic (Greenberg, 1987).

Beyond the Language Family

As mentioned previously, there can be various degrees of resemblance between language families and the levels of relationship can be quantified lexicostatistically and described in terms of stock and phylum. But besides hypotheses of wider relationships based purely on lexicostatistics, there are hypotheses about possible relationships between families using standard techniques of reconstruction or mixtures of standard methodology and lexicostatistics. The Nostratic hypothesis is one of the boldest and most controversial approaches; largely the work of Aharon Dolgopolsky and Vladimir Illich-Svitych, the hypothesis claims that there is a macrofamily consisting of Indo-European, Semitic, Berber, Kartvelian, Uralic, Altaic, Korean, Japanese, and Dravidian (Dolgopolsky, 1998). Other work includes that of Paul Benedict, who proposed an Austro-Tai family combining Hmong-Mien (Miao-Yao), the Tai-Kadai (or Daic) family, and Austronesian. Joseph Greenberg considered that these three recognized families plus Austroasiatic form an Austric family (Ruhlen, 1991: 152–156).

Isolates

A number of languages appear to belong to no family, though in many cases they are presumably remnants of families. The following languages are examples:

- Ainu (spoken in Japan)
- Burushaski (spoken in northern Pakistan)
- Basque (spoken in the Pyrenees)
- Elamite (an extinct language of southwestern Iran; it has been claimed to be related to the Dravidian languages of southern India)
- Japanese and the Ryukyuan dialects (the latter spoken in the Ryukyu Islands of Japan)
- Ket (spoken in the Yenisei Basin, Siberia)
- Korean
- Nivkh (spoken in eastern Siberia, including Sakhalin Island)
- Sumerian (extinct language of Mesopotamia with records from the 3rd millennium B.C.)
- Yukaghir (spoken in eastern Siberia).

For most of these languages, hypotheses are put forward from time to time linking them with other languages. A number of scholars include Japanese or Korean, or both, in the Altaic family, and some would include Yukaghir in the Uralic family.

Pidgins and Creoles

Where people find themselves in contact but without a common language, a 'pidgin' develops, which is a simplified form of language. The pidgin usually combines elements from more than one language, but in most cases the bulk of the lexicon comes from one particular language. A number of pidgins developed in the context of European colonial expansion from the 15th to the 19th centuries in places where workers, often slaves, from different language backgrounds were faced with an unfamiliar European language and in many cases unfamiliar languages of fellow workers. Where later generations learned these pidgins as their native language, the pidgins expanded to be full languages. Such languages are known as 'creoles'. In terms of classification, pidgins and creoles do not lend themselves to the hierarchical taxonomy wherein each language has a single ancestor. However, they tend to be identified in terms of which language supplies most of the vocabulary. The list of the pidgins and creoles included in this work, given in Table 1, shows the main source of the lexicon and where the pidgin or creole is, or was, spoken.

Table 1 Pidgins and creoles

Language	*Main source of the lexicon*	*Location*
Bislama	English	Vanuatu
Cape Verdean creole	Portuguese	Cape Verde
Fanagolo	Bantu languages (e.g., Xhosa, Zulu)	Southern Africa
Gullah	English	Sea Islands of South Carolina
Hawaiian creole	English	Hawaii, United States
Krio	English	Sierra Leone
Louisiana creole	French	Lousiana, United States
Mobilian jargon	Choctaw, Chickasaw	Southeastern United States (extinct)
Palenquero	Spanish	Colombia
Papamiento	Portuguese, Spanish	Aruba, Bonaire, Curaçao
Russenorsk	Russian, Norwegian	Arctic (extinct)
Sango	Ngbandi, French	Central African Republic
Sranan	English	Surinam
Tok Pisin	English	New Guinea
Yanito	English, Spanish	Gibraltar

Status of the Groupings Used in the Classification

This section contains a list of language families and other groupings in alphabetic order with an indication of the status of the groupings, i.e. whether the labels represent generally accepted families, controversial families or larger entities. It should be noted that while the list covers most of the language families of the world, it is not a complete catalogue of the world's languages, which total somewhere near 5000.

Afroasiatic Languages

There are various classifications of Afroasiatic languages. The one used here recognizes six families: Ancient Egyptian and its successor, Coptic; Berber (northwest corner of Africa); Chadic (Niger and Chad); Cushitic (Somalia and eastern Sudan); Omotic (southern Ethiopia); and Semitic. Semitic has three branches. The eastern branch is represented by Akkadian, which was spoken in Mesopotamia from the 3rd to the 1st millennium B.C. The southern branch is represented by the Ethiopian languages (Amharic, Tigrinya, and the extinct Ge'ez). The central branch, which is centered around the eastern end of the Mediterranean, includes the dead languages Phoenician, Syriac, and Ugaritic, plus Aramaic, a language in which parts of the Bible are written and which is still spoken; Hebrew, which has been brought back to life as the language of Israel; and Arabic, which, as the language of Islam, has spread over northern Africa and the Middle East.

Altaic Languages

Altaic is a widely, though not universally, accepted language family covering three branches: Turkic, Mongolic, and Tungusic, represented in this work by Evenki. The Turkic languages, which include Turkish, extend across from the Balkans through Turkey across central Asia to Siberia. The Mongolic languages are centered on Mongolia and the Tungusic languages in Siberia and northern China. If Altaic is rejected as a family, then we have three separate families rather than three branches of a family. These languages are typologically similar in that they are agglutinative, and they represent the classic SOV word-order type with SOV word order, postpositions, and preposed genitives. Some linguists would include Japanese and/or Korean in the Altaic family.

Australian Languages

The languages of the Australian mainland look as if they are related, but no detailed reconstruction of a protolanguage has been undertaken and it is unlikely that such a reconstruction will be possible. These languages have been classified lexicostatistically, i.e., by counting percentages of common vocabulary. This classification currently recognizes about a score of lexicostatistical families, with one of them, Pama-Nyungan, covering most of the mainland. Some genetic groupings are recognizable within Pama-Nyungan, and some of the other lexicostatistical families can be shown to be true families, such as the Tangkic family, which includes Kayardild, and West Barkly, which includes Wambaya. Tiwi is the sole member of the Tiwian family. Dixon (2002: 674) suggests that the similar-looking Daly group of languages (represented in this work by Ngan'gityemerri) is an areal group rather than a genetic one. Records of the extinct Tasmanian languages consist almost entirely of amateur word lists. These show very few resemblances to the languages of the mainland. Joseph Greenberg classified the Tasmanian languages, the Papuan languages, and the languages of the Andaman Islands in an Indo-Pacific phylum (Ruhlen, 1991). This grouping has been disregarded by almost all other linguists.

Austroasiatic Languages

The Austroasiatic classification comprises two branches: the Munda languages of northeast India, which includes Santali, and the more scattered Mon-Khmer branch, which includes Mon (southeastern Myanmar (Burma)), Khmer (or Cambodian, the official language of Cambodia), Khasi (northeast India), Wa (southwest Yunnan, China), and Vietnamese. Vietnamese is interesting from the point of view of classification. It has been so influenced by Chinese that as well as borrowing large numbers of Chinese words, it has reduced the form of roots and developed tones so that the language looks like a Chinese language.

Austronesian Languages

The Austronesian language family contains over 1000 languages. In the most widely used classification, there are four branches, Paiwanic, Tsouic, Ayatalic, and Malayo-Polynesian. The first three are the indigenous languages of Taiwan and are collectively known as the Formosan languages. The extra-Formosan languages, which are assumed to have emanated from Taiwan, make up the Malayo-Polynesian branch, which is spread from Madagascar in the western Indian Ocean, where Malagasy is spoken, to Easter Island in the eastern Pacific. Oversimplifying somewhat, we can consider there are three subbranches: western, which takes in the languages of the Philippines, Indonesia, and Malaysia as well as

Malagasy and Hawaiian; central, represented in this work by the Flores languages and Malukan languages; and Oceanic, which covers languages such as Fijian, Maori, Samoan, Tahitian, and Tongan.

Caucasian Languages

The languages of the Caucasus comprise a South Caucasian or Kartvelian family, represented here by Georgian, and the North Caucasian languages, with a northwestern sub-branch, represented here by Abkhaz, and a northeastern sub-branch, represented by Lak. It is not quite certain that the northwestern branch and northeastern Branch are branches of a single family, and it is even more uncertain that South Caucasian and North Caucasian families form a genetic group, but the label 'Caucasian languages' is useful since the two groups share some features and are all quite distinct from surrounding languages.

Chukotko-Kamchatkan Languages

This is a small family of languages spoken on the Chukotka and Kamchatka peninsulas of Siberia.

Dravidian Languages

This language family is concentrated in southern India. Some branches are recognizable. Dravidian proper includes Gondi, Kurukh, and Telegu; the southern branch includes Kannada, Malayalam, Tamil, and Toda, and the northwestern branch includes Brahui.

Eskimo-Aleut

The Eskimo-Aleut language family has two primary branches. The Aleut branch is spoken in the Aleutian Islands and the Eskimo languages are found in Siberia, Alaska, Canada, and Greenland. The latter branch is represented here by Inupiaq and West Greenlandic.

Indo-European

Indo-European is the most widely studied of all language families and has a well-articulated sub-grouping based on the comparative method, though details of the classification are subject to dispute from time to time. This family of languages contains a number of branches containing a single language (or group of dialects), namely, Albanian, Armenian, Hellenic (Greek), and two dead languages, records of which came to light only in the 20th century. One dead language is Hittite, which was spoken in Anatolia (modern Turkey). There are records of Hittite from the latter part of the second millennium B.C. The other dead language, Tocharian, the easternmost Indo-European language, was spoken in what is now the Xinjiang province of western China. There are records of Tocharian from the period 500–700 A.D.

Among other branches are the following Indo-European languages:

- Baltic contains Lithuanian and Latvian, and Slavic, the earliest records of which are in Old Church Slavonic and date from the 11th and 12th centuries. Modern Slavic languages include Polish, Sorbian, Czech, and Slovak (western sub-branch); Bulgarian, Macedonian, Slovene, and the 'Serbian-Croatian-Bosnian complex' (southern sub-branch); and Russian, Belorussian, and Ukrainian (eastern sub-branch). Some linguists would classify Baltic and Slavic as sub-branches of a Balto-Slavic branch.
- Celtic is usually divided into two sub-branches: the Brythonic branch, which contains Breton, Cornish, Welsh, and possibly Pictish, about which little is known, and the Goidelic branch, which contains Scots Gaelic.
- Germanic contains three sub-branches. The eastern sub-branch is represented by the extinct Gothic; the northern sub-branch, by the Scandinavian languages (Danish, Icelandic, Norwegian, Swedish); and the western sub-branch, by German (including High German, Yiddish, and Low German), Frisian, Dutch, and its South African derivative, Afrikaans, and various forms of English, including Scots.
- Indo-Iranian is a large branch containing two large sub-branches, Indo-Aryan (or Indic) and Iranian. Indo-Aryan covers Sanskrit, the language of the Hindu sacred texts; Pali, the language of the Hinayana Buddhist canon; plus Bengalic, the Dardic languages, Dhivehi, Domari, Gujerati, Hindi, Hindustani, Kashmiri, Lahnda, Marathi, Nepali, Punjabi, Sindhi, Sinhala, and Urdu, all of which are spoken in India, Pakistan, and Bangladesh, plus Romani, the language of scattered Gypsy communities. Iranian covers Avestan, the language of the Zoroastrian scriptures, plus Bactrian, Baluchi, Chorasmian, Khotanese, Kurdish, Ossetic, Pahlavi (Middle Persian), Pashto, Persian, Sogdian, and Tajik.
- Italic contains a number of extinct languages of Italy, one of which, Latin, was spread via the political dominance of Rome. The descendants of Latin, known collectively as the Romance Languages, include several national languages (French, Italian, Portuguese, Romanian, and Spanish) as well as Catalan (northeastern Spain), Galician (northwestern Spain), Jerriais (Jersey), Occitan (southern France), Rhaeto-Romance (eastern Switzerland and northeastern Italy), and Sardinian.

Khoesan Languages

The Khoesan group of languages is spoken by the Khoekhoe and San peoples of southern Africa. The group is often described as having three branches, but the branches are probably separate families. Two languages of northern Tanzania, Hadza and Sandawe, are also included in the group in most reference works, but it is not clear that they are genetically related to any of the southern families.

Languages of the Americas

As mentioned in the preceding section on lexicostatistics, Joseph Greenberg classified all of the languages of the Americas in one vast Amerind family, except for Na-Dene (mainly in northwestern part of North America) and Eskimo-Aleut in the Arctic. This classification is generally rejected and most scholars would recognize some scores of separate families in Greenberg's Amerind, though allowing that some of these can be grouped into stocks. We have followed a widespread convention of breaking up the languages of the Americas into three geographical regions: North America, Central America, and South America. This is largely to reduce a very large area to manageable chunks. We have considered Eskimo-Aleut separately from the languages of the Americas since it is not confined to North America.

Languages of North America

- The Algonquian languages are found in the eastern part of North America and westward into Alberta and Montana, and the Ritwan languages (Wiyot and Yurok) are found in northern California. Mithun (1999: 327) recognizes Eastern Algonquian, Central and Plains Algonquian, and Ritwan as branches of an Algic family. Algonquian is represented in this work by Cree and Mitchif. Mitchif is a creole, but, unlike most creoles, it did not arise from a pidgin. It retains the complex verbal morphology of Cree, and noun phrases show distinctions of number, gender, and definiteness, as in French.
- The Caddoan language family belongs to the Great Plains of the midwestern United States.
- The Hokan group of languages is centered in California. It is not established that these languages form a family. Among the Hokan languages is the Pomoan family of northern California.
- The Iroquoian language family of southeastern Canada and the eastern United States is represented in this work by Oneida (Northern Iroquoian) and Cherokee (Southern Iroquoian).
- The Keres language consists of a number of dialects spoken in New Mexico.
- The Muskogean language family of the southeastern United States includes Choctaw (Mississippi) and Creek (Alabama and Georgia).
- The Na-Dene language family includes Tlingit, Eyak, and the large Athapaskan branch. Most of these languages belong to Alaska and western Canada, but there is an enclave of Athapascan in the southwest of the United States. Navajo (Navaho) is spoken in Arizona, New Mexico, and Utah.
- The Penutian group of languages or stock belongs to the west of North America, from British Columbia to California.
- Languages of the Salishan family are spoken in British Columbia and the northwest of the United States.
- The Siouan family of languages covered a vast area of the Great Plains and included Crow, Lakota, and Omaha-Ponca.
- The Wakashan language family is mainly from Vancouver Island, British Columbia, and is represented by Nuuchahnulth (Nootka).

Languages of Central America

- Languages of the Chibchan family are spoken in Nicaragua, Costa Rica, Panama, western Colombia, and Ecuador, and the Paezan languages are spoken in Colombia.
- The Mayan family of languages is spoken in southeastern Mexico and Guatemala.
- The Misumalpan language family is found in western Honduras and western Nicaragua.
- The Mixe-Zoquean language family is found in southern Mexico.
- The Oto-Manguean language, represented here by Zapotecan, is found in Southern Mexico.
- The Uto-Aztecan language family is found mainly in the southwest of the United States and Mexico, but extends as far north as Idaho. This family includes Cupeño, Hopi, Tohono O'odham, and Nahuatl, the language of the Aztec civilization.

Languages of South America

- The most widely spoken native language of South America is Quechua. It is spoken in Peru, Ecuador, and Bolivia, extending north into Colombia and extending south into northern Chile and northwestern Argentina. It shares similarities with Aymará and the two are sometimes grouped in an Andean family, but this is not generally accepted, since it is not agreed whether the resemblances are genetic or arise from contact.

- The large Arawak language family is widespread, ranging from Honduras in Central America to Brazil in South America, and formerly to Paraguay and Argentina. The Arawak language in this work is Tariana, of Brazil.
- The large Carib language family is found in Brazil and the countries of South America north of Brazil.
- The Choco language family is found in Brazil.
- The languages of the Panoan family are found in Peru and neighboring parts of Bolivia and Brazil.
- Macro-Jê is a grouping of languages that have been considered to be related to the Jê family. These languages are located in Brazil.
- The Mapudungan language is spoken in Chile and Argentina. It has no clear genetic affiliation.
- The Tucanoan language family is found in western Brazil and neighboring parts of Colombia, Ecuador, and Brazil.
- The Tupian language family is located in Brazil. The Tupí-Guaraní sub-group is also found in Brazil, but various members of the sub-group are found in Bolivia, Paraguay, and Argentina. Guaraní is an official language of Paraguay, along with Spanish.

Niger-Congo Languages

This is a very large language family, with about 1000 members. It is spread over southern Africa. There are various classifications, including some that are hierarchical with several levels. We have adopted a flat classification with eight branches:

- The Kordofanian group of languages is spoken in Sudan. In some classifications, a Niger-Kordofanian family is recognized, with Kordofanian and Niger-Congo as the primary branches.
- The Atlantic Congo language sub-group is located in the far west of Africa from Liberia to Senegal. It includes Fula and Wolof.
- Languages of the Kru sub-group are spoken in Ivory Coast and Liberia.
- The Mande language sub-group is found from Senegal to Burkina Faso (Upper Volta) and Ivory Coast.
- The Gur (Voltaic) language sub-group is spoken in Mali, Burkina Faso, and Ghana, and extends east into Nigeria. In some classifications, Dogon is not assigned to any branch; in others, it is assigned to the Gur sub-branch.
- The Kwa sub-group of languages extends from Liberia to Nigeria.
- The Benue-Congo language sub-group covers a very large part of southern Africa. This branch includes Efik, Yukuben, and Mambila. The very large Bantu language group, which includes Kikuyu, Kinyarwanda, Nyanja, Shona, Swahili, Xhosa, and Zulu, is a sub-group of Benue-Congo and hence a sub-sub-group of Niger-Congo.
- The Adama-Ubangi language sub-group is spoken in a band running across Africa from Nigeria to Sudan.

Nilo-Saharan

The languages of the Nilo-Saharan family are found mainly in northeastern and north-central Africa. They include Dinka, Kanuri, Luo, and the Songhay languages.

Papuan Languages

The label 'Papuan' has no genetic significance. It is defined negatively as the non-Austronesian languages of New Guinea and surrounding islands. It covers about 750 languages in New Guinea and another 50 or so on neighboring islands from Timor to the Solomons. These languages can be classified into 23 families and 10 isolates. One very large family, the Trans-New Guinea family, covers most of New Guinea and is also found on some of the neighboring islands. It contains a number of branches, including the Madang languages. Other families include Sepik, represented in this work by Manambu of the Ndu subgroup, Skou, Torricelli, and West Papuan. Also included in this work is an article on several of the Papuan languages of the central Solomons.

Sino-Tibetan

The Sino-Tibetan languages include the Sinitic family and Tibeto-Burman. Sinitic can be equated with Chinese, but Chinese is popularly understood to be a single language, whereas in fact it is more like a family of languages, one of which, Mandarin Chinese, is the standard, based largely on the Beijing dialect. Tibeto-Burman takes in a number of genetically related languages, including Tibetan and Burmese, but there is no consensus about the details of the classification. Whether Tibeto-Burman and Sinitic are genetically related is not agreed, but there are some apparent cognates.

Tai Languages

The Tai, or Daic, language family is centered in Laos and Thailand and includes the national languages of these two countries, Lao (or Laotian) and Thai. The family is also represented in Burma, southern China, northern Vietnam, and on Hainan Island in the Gulf of Tonkin. Lao and Thai are mutually comprehensible. A purely linguistic classification would recognize a chain of Tai dialects across the two countries that included the national languages.

Uralic Languages

The Uralic languages are a family of languages spoken in northeastern Europe, extending across northern Russia into northwestern Siberia. There are two major branches, the Samoyed branch, represented in this work by Nenets, spoken in northern Russia, and Finno-Ugric, which includes Estonian, Finnish, and Saami (spoken in northern Norway, Sweden, and Finland), as well as Hungarian, the national language of Hungary, which is separated from the rest of the family. Some would include Yuhaghir in the Uralic family, others would combine Uralic and Altaic into a larger family.

See also: There are separate articles on each of the languages and language families shown in the classification appended to this article. There is also an alphabetical list of all the language articles in the classified index.

Introduction

In the last two decades, the production of textual documents in digital form has increased exponentially, due to the increased availability of inexpensive hardware and software for generating digital text (e.g., personal computers, word processors) and for digitizing textual data not in digital form (e.g., scanners, optical character recognition software). As a consequence, there is an ever-increasing need for mechanized solutions for organizing the vast quantity of digital texts that are being produced, with an eye toward their future use. The design of such solutions has traditionally been the object of study of information retrieval (IR), the discipline that, broadly speaking, is concerned with the computer-mediated access to data with poorly specified semantics.

There are two main directions for providing convenient access to a large, unstructured repository of text:

- Providing powerful tools for searching relevant documents within this repository. This is the aim of text search (*see* **Document Retrieval, Automatic**), a subdiscipline of IR concerned with building systems that take as input a natural language query and return, as a result, a list of documents ranked according to their estimated degree of relevance to the user's information need. Nowadays the tip of the iceberg of text search is represented by Web search engines (*see* **Web Searching**), but commercial solutions for the text search problem were being delivered decades before the very birth of the Web.
- Providing powerful tools for turning this unstructured repository into a structured one, thereby easing storage, search, and browsing. This is the aim of text classification (TC), a discipline at the crossroads of IR, machine learning (ML), and (statistical)

Introduction

In the last two decades, the production of textual documents in digital form has increased exponentially, due to the increased availability of inexpensive hardware and software for generating digital text (e.g., personal computers, word processors) and for digitizing textual data not in digital form (e.g., scanners, optical character recognition software). As a consequence, there is an ever-increasing need for mechanized solutions for organizing the vast quantity of digital texts that are being produced, with an eye toward their future use. The design of such solutions has traditionally been the object of study of information retrieval (IR), the discipline that, broadly speaking, is concerned with the computer-mediated access to data with poorly specified semantics.

There are two main directions for providing convenient access to a large, unstructured repository of text:

- Providing powerful tools for searching relevant documents within this repository. This is the aim of text search (*see* **Document Retrieval, Automatic**), a subdiscipline of IR concerned with building systems that take as input a natural language query and return, as a result, a list of documents ranked according to their estimated degree of relevance to the user's information need. Nowadays the tip of the iceberg of text search is represented by Web search engines (*see* **Web Searching**), but commercial solutions for the text search problem were being delivered decades before the very birth of the Web.
- Providing powerful tools for turning this unstructured repository into a structured one, thereby easing storage, search, and browsing. This is the aim of text classification (TC), a discipline at the crossroads of IR, machine learning (ML), and (statistical)

natural language processing, concerned with building systems that partition an unstructured collection of documents into meaningful groups (Sebastiani, 2002).

Text Clustering and Text Categorization

There are two main variants of TC. The first is **text clustering**, which is characterized by the fact that only the desired number of groups (or clusters) is known in advance: no indication as to the semantics of these groups is instead given as input. The second variant is **text categorization**, whereby the input to the system consists not only of the number of categories (or classes), but also of some specification of their semantics. In the most frequent case, this specification consists in a set of labels, one for each category and usually consisting of a noun or other short natural language expression, and in a set of example labeled texts, i.e., texts whose membership or nonmembership in each of the categories is known. Clustering may thus be seen as the task of finding a latent but as yet undetected group structure in the repository, while categorization can be seen as the task of structuring the repository according to a group structure known in advance. In logical-philosophical terms, we can see clustering as the task of determining both the extensional and intensional level (*see* **Extensionality and Intensionality**) of a previously unknown group structure, and categorization as determining the extensional level only of a group structure whose intensional level is known.

It is the latter task that will be the focus of this article (text clustering is covered elsewhere in this volume – *see* **Text Mining**). From now on we will thus use the expressions 'text classification' and 'text categorization' interchangeably (abbreviated as TC), and the expression '(text) classifier' to denote a system capable of performing automatic TC.

Note that the central notion of TC, that of membership of a document d_j in a class c_i based on the semantics of d_j and c_i, is an inherently subjective notion, since the semantics of d_j and c_i cannot be formally specified. Different classifiers (be they humans or machines) might thus disagree on whether d_j belongs to c_i. This means that membership cannot be determined with certainty, which in turn means that any classifier (be it human or machine) will be prone to misclassification errors. As a consequence, it is customary to evaluate automatic text classifiers by applying them to a set of labeled (i.e., preclassified) documents (a set that here plays the role of a gold standard), so that the accuracy (or effectiveness) of the classifier can be measured by the degree of coincidence between its classification decisions and the labels originally attached to the preclassified documents.

Single-Label and Multi-Label Text Categorization

TC itself admits of two important variants: single-label TC and multi-label TC. Given as input the set of categorories $C = \{c_1, \ldots, c_m\}$, single-label TC is the task of attributing, to each document d_j in the repository, **the** category to which it belongs. Multi-label TC, instead, deals with the case in which each document d_j may in principle belong to zero, one, or more than one category; it thus comes down to deciding, for each category c_i in C, whether a given document d_j belongs or does not belong to c_i.

The technologies for coping with either single-label or multi-label TCs are slightly different (the former problem often being somehow more challenging), especially concerning the phases of feature selection, classifier learning, and classifier evaluation (see below). In a real application, it is thus of fundamental importance to identify whether the application requires single-label or multi-label TC from the beginning.

Hard or Soft Text Categorization

Taking a binary decision, yes or no, as to whether a document d_j belongs to a category c_i, is sometimes referred to as a 'hard' categorization decision. This is the kind of decisions that are taken by autonomous text classifiers, i.e., software systems that need to decide and act accordingly without human supervision. A different type of decision, sometimes referred to as a 'soft' categorization decision, is one which consists of attributing a numeric score (e.g., between 0 and 1) to the pair (d_j, c_i), reflecting the degree of confidence of the classifier in the fact that d_j belongs to c_i. This allows, for instance, ranking a set of documents in terms of their estimated appropriateness for category c_i, or ranking a set of categories in terms of their estimated appropriateness for d_j. Such rankings are often useful for nonautonomous, interactive classifiers, i.e., systems whose goal is to recommend a categorization decision to a human expert, who is responsible for making the final decision. For instance, in a single-label TC task a human expert in charge of the final classification decision may take advantage of a system that preranks the categories in terms of their estimated appropriateness to a given document d_j.

Again, the technologies for coping with either soft or hard categorization decisions are slightly different, especially concerning the phases of classifier learning and classifier evaluation (see below). In any real-world application, it is thus important to establish whether the task is one requiring soft or hard decisions from the beginning.

Applications

Maron's seminal paper (Maron, 1961) is usually taken to mark the official birth date of TC, which at the time was called automatic indexing; this name reflected that the main (or only) application that was then envisaged for TC was automatically indexing (i.e., generating internal representations for) scientific articles for Boolean IR systems (*see* **Indexing, Automatic**). In fact, since index terms for these representations were drawn from a fixed, predefined set of such terms, we can regard this type of indexing as an instance of TC (where index terms play the role of categories). The importance of TC increased in the late 1980s and early 1990s with the need to organize the increasingly larger quantities of digital text being handled in organizations at all levels. Since then, frequently pursued applications of TC technology have been newswire filtering, i.e., the grouping, according to thematic classes of interest, of news stories produced by news agencies, thus allowing personalized delivery of information to customers according to their profiles of interest (Hayes and Weinstein, 1990); patent classification, i.e., the organization of patents and patent applications into specialized taxonomies, so as to ease the detection of existing patents related to a new patent application (Fall *et al.*, 2003); and Web page classification, i.e., the grouping of Web pages (or sites) according to the taxonomic classification schemes typical of Web portals (Dumais and Chen, 2000).

The applications above all have a certain thematic flavor, in the sense that categories tend to coincide with topics, or themes. However, TC technology has been applied to real-world problems that are not thematic in nature, among which spam filtering, i.e., the grouping of personal e-mail messages into the two classes LEGITIMATE and SPAM, so as to provide effective user shields against unsolicited bulk mailings (Drucker *et al.*, 1999); authorship attribution, i.e., the automatic identification of the author of a text among a predefined set of candidates (Diederich *et al.*, 2003) (*see* **Authorship Attribution: Statistical and Computational Methods**); author gender detection, i.e., a special case of the previous task in which the issue is deciding whether the author of the text is a MALE or a FEMALE (Koppel *et al.*, 2002); genre classification, i.e., the identification of the nontopical communicative goal of the text (such as determining if a product description is a PRODUCTREVIEW or an ADVERTISEMENT) (Stamatatos *et al.*, 2000); survey coding, i.e., the classification of respondents to a survey based on the textual answers they have returned to an open-ended question (Giorgetti and Sebastiani, 2003); or even sentiment classification, as in deciding if a product review is a THUMBSUP or a THUMBSDOWN (Turney and Littman, 2003).

Techniques

Approaches

In the 1980s, the most popular approach to TC was one based on knowledge engineering, whereby a knowledge engineer and a domain expert working together would build an expert system capable of automatically classifying text. Typically, such an expert system would consist of a set of 'if ... then ...' rules, to the effect that a document was assigned to the class specified in the 'then' clause only if the linguistic expressions (typically: words) specified in the 'if' part occurred in the document. The drawback of this approach was the high cost in terms of human-power required for (i) defining the rule set, and (ii) for maintaining it, i.e., for updating the rule set as a result of possible subsequent additions or deletions of classes or as a result of shifts in the meaning of the existing classes.

In the 1990s, this approach was superseded by the machine-learning approach, whereby a general inductive process (the learner) is fed with a set of example (training) documents preclassified according to the categories of interest. By observing the characteristics of the training documents, the learner may generate a model (the classifier) of the conditions that are satisfied by the documents belonging to the categories considered. This model can subsequently be applied to new, unlabeled documents for classifying them according to these categories.

This approach has several advantages over the knowledge engineering approach. First of all, a higher degree of automation is introduced: the engineer needs to build not a text classifier, but an automatic builder of text classifiers (the learner). Once built, the learner can then be applied to generating many different classifiers, for many different domains and applications: one only needs to feed it with the appropriate sets of training documents. By the same token, the above-mentioned problem of maintaining a classifier is solved by feeding new training documents appropriate for the revised set of classes. Many inductive learners are available off the shelf; if one of these is used, the only human power needed in setting up a TC system is that for manually classifying the documents to be used for training. For performing this latter task, less skilled human power than for building an expert system is needed, which is also advantageous. It should also be noted that if an organization has previously relied on manual work for classifying documents, then many preclassified documents are already available to be used as training documents when the organization decides to automate the process.

Most importantly, one of the advantages of the ML approach is that the accuracy of classifiers built by these techniques now often rivals that of human

professionals, and usually exceeds that of classifiers built by knowledge engineering methods. This has brought about a wider and wider acceptance of learning methods even outside academia. While for certain applications such as spam filtering a combination of ML and knowledge engineering still lies at the basis of several commercial systems, it is fair to say that in most other TC applications (especially of the thematic type), the adoption of ML technology has been widespread.

Note that the ML approach is especially suited to the case in which no additional knowledge (of a procedural or declarative nature) of the meaning of the categories is available, since in this case the classification rules can be determined only on the basis of knowledge extracted from the training documents. This case is the most frequent one, and is thus the usual focus of TC research. Solutions devised for the case in which no additional knowledge is available are extremely general, since they do not presuppose the existence of e.g., additional lexicosemantic resources that, in real-life situations, might be either unavailable or expensive to create (*see* **Computational Lexicons and Dictionaries**). A further reason why TC research rarely tackles the case of additionally available external knowledge is that these sources of knowledge may vary widely in type and format, thereby making each instance of their application to TC a case in its own, from which any lesson learned can hardly be exported to different application contexts. When in a given application external knowledge of some kind is available, heuristic techniques of any nature may be adopted in order to leverage on these data, either in combination or in isolation from the IR and ML techniques we will discuss here. However, it should be noted that past research has not been able to show any substantial benefit from the use of external resources (such as lexicons, thesauri, or ontologies) in TC.

As previously noted, the meaning of categories is subjective. The ML techniques used for TC, rather than trying to learn a supposedly perfect classifier (a gold standard of dubious existence), strive to reproduce the subjective judgment of the expert who has labeled the training documents, and do this by examining the manifestations of this judgment, i.e., the documents that the expert has manually classified. The kind of learning that these ML techniques engage in is usually called supervised learning, since it is supervised, or facilitated, by the knowledge of the preclassified data.

Learning Text Classifiers

Many different types of supervised learners have been used in TC (Sebastiani, 2002), including probabilistic 'naive Bayesian' methods, Bayesian networks, regression methods, decision trees, Boolean decision rules, neural networks, incremental or batch methods for learning linear classifiers, example-based methods, classifier ensembles (including boosting methods), and support vector machines. While all of these techniques still retain their popularity, it is fair to say that in recent years support vector machines (Joachims, 1998) and boosting (Schapire and Singer, 2000) have been the two dominant learning methods in TC. This seems attributable to a combination of two factors: (i) these two methods have strong justifications in terms of computational learning theory, and (ii) in comparative experiments on widely accepted benchmarks, they have outperformed all other competing approaches. An additional factor that has determined their success is the free availability, at least for research purposes, of well-known software packages based on these methods, such as SVMlight and BoosTexter.

Building Internal Representations for Documents

The learners discussed above cannot operate on the documents as they are, but require the documents to be given internal representations that the learners can make sense of. The same is true of the classifiers, once they have been built by learners. It is thus customary to transform all the documents (i.e., those that are used in the training phase, the testing phase, or the operational phase of the classifier) into internal representations by means of methods used in text search, where the same need is also present (*see* **Indexing, Automatic**). Accordingly, a document is usually represented by a vector lying in a vector space whose dimensions correspond to the terms that occur in the training set, and the value of each individual entry corresponds to the weight that the term in question has for the document.

In TC applications of the thematic kind, the set of terms is usually made to coincide with the set of content-bearing words (which means all words but topic-neutral ones such as articles, prepositions, etc.), possibly reduced to their morphological roots (stems – *see* **Stemming**) so as to avoid excessive stochastic dependence among different dimensions of the vector. Weights for these words are meant to reflect the importance that the word has in determining the semantics of the document it occurs in, and are automatically computed by weighting functions. These functions usually rely on intuitions of a statistical kind, such as (i) the more often a term occurs in a document, the more important it is for that document; and (ii) the more documents a term appears in, the less important it is in characterizing the semantics of a document it occurs in.

In TC applications of a nonthematic nature, the opposite is often true. For instance, it is the frequency

of use of articles, prepositions, and punctuation (together with many other stylistic features) that may be a helpful clue in authorship attribution, while it is more unlikely that the frequencies of use of content-bearing words can be of help (*see* **Computational Stylistics**). This shows that choosing the right dimensions of the vector space for the right classification task requires a deep understanding, on the part of the engineer, of the nature of the task.

It is fairly evident from the above discussion that internal representations used in TC applications are, from the standpoint of linguistic analysis, extremely primitive: with the possible exception of applications in sentiment classification (Turney and Littman, 2003), hardly any sophisticated linguistic analysis is usually attempted in order to provide a more faithful rendition of the semantics of the text. This is because previous attempts at applying state-of-the-art natural language processing techniques (including techniques for parsing text robustly (Moschitti and Basili, 2004), extracting collocations (Koster and Seutter, 2003), performing word sense disambiguation (Kehagias *et al.*, 2003), etc.) have not shown any substantial benefit with respect to the basic representations outlined above.

Reducing the Dimensionality of the Vectors

The techniques described in the previous section tend to generate very large vectors, with sizes in the tens of thousands. This situation is problematic in TC, since the efficiency of many learning devices (e.g., neural networks) tends to degrade rapidly with the size of the vectors. In TC applications, it is thus customary to run a dimensionality reduction pass before starting to build the internal representations of the documents. Basically, this means identifying a new vector space in which to represent the documents, with a much smaller number of dimensions than the original one. Several techniques for dimensionality reduction have been devised within TC (or, more often, borrowed from the fields of ML and pattern recognition).

An important class of such techniques is that of feature extraction methods (examples of which are term clustering methods and latent semantic indexing – *see* **Latent Semantic Analysis**). Feature extraction methods define a new vector space in which each dimension is a combination of some (or all) of the original dimensions; their effect is usually a reduction of both the dimensionality of the vectors and the overall stochastic dependence among dimensions.

An even more important class of dimensionality reduction techniques is that of feature selection methods, which do not attempt to generate new terms, but try to select the best ones from the original set. The measure of quality for a term is its expected impact on the accuracy of the resulting classifier. To measure this, feature selection functions are employed for scoring each term according to this expected impact, so that the highest scoring ones can be retained for the new vector space. These functions mostly come from statistics (e.g., Chi-square) or information theory (e.g., mutual information, also known as information gain), and tend to encode (each one in their own way) the intuition that the best terms for classification purposes are the ones that are distributed most differently across the different categories.

Challenges

TC, especially in its ML incarnation, is today a fairly mature technology that has delivered working solutions in a number of applicative contexts. Interest in TC has grown exponentially in the last 10 years, from researchers and developers alike.

For IR researchers, this interest is one particular aspect of a general movement toward leveraging user data for taming the inherent subjectivity of the IR task, i.e., taming the fact that it is the user, and only the user, who can say whether a given item of information is relevant to a query she has issued to a Web search engine, or relevant to a private folder of hers in which documents should be filed according to content. Wherever there are predefined classes, documents previously (and manually) classified by the user are often available; as a consequence, these latter data can be exploited for automatically learning the (extensional) meaning that the user attributes to the categories, thereby reaching accuracy levels that would be unthinkable if these data were unavailable.

For ML researchers, this interest is because TC applications prove a challenging benchmark for their newly developed techniques, since these applications usually feature extremely high-dimensional vector spaces and provide large quantities of test data. In the last 5 years, this has resulted in more and more ML researchers adopting TC as one of their benchmark applications of choice, which means that cutting-edge ML techniques are being applied to TC with minimal delay since their original invention.

For application developers, this interest is mainly due to the enormously increased need to handle larger and larger quantities of documents, a need emphasized by increased connectivity and availability of document bases of all types at all levels in the information chain. But this interest also results from TC techniques having reached accuracy levels that often rival the performance of trained professionals, levels that can be achieved with high efficiency on standard hardware and software resources. This means that more and more organizations are automating all their activities that can be cast as TC tasks. Still, a number of challenges remain for TC research.

The first and foremost challenge is to deliver high accuracy in **all** applicative contexts. While highly effective classifiers have been produced for applicative domains such as the thematic classification of professionally authored text (such as newswire stories), in other domains reported accuracies are far from satisfying. Such applicative contexts include the classification of Web pages (where the use of text is more varied and obeys rules different from the ones of linear verbal communication), spam filtering (a task which has an adversarial nature, in that spammers adapt their spamming strategies so as to circumvent the latest spam filtering technologies), authorship attribution (where current technology is not yet able to tackle the inherent stylistic variability among texts written by the same author), and sentiment classification (which requires much more sophisticated linguistic analysis than classification by topic).

A second important challenge is to bypass the document labeling bottleneck, i.e., tackling the facts that labeled documents for use in the training phase are not always available, and that labeling (i.e., manually classifying) documents is costly. To this end, semisupervised methods have been proposed that allow building classifiers from a small sample of labeled documents and a (usually larger) sample of unlabeled documents (Nigam and Ghani, 2000; Nigam *et al.*, 2000). However, the problem of learning text classifiers mainly from unlabeled data unfortunately is still open.

Classifiers and Noun Classes: Semantics

A Y Aikhenvald, La Trobe University, Bundoora, Australia

© 2006 Elsevier Ltd. All rights reserved.

Almost all languages have some grammatical means for the linguistic categorization of nouns and nominals. The continuum of noun categorization devices covers a range of devices, from the lexical numeral classifiers of Southeast Asia to the highly grammaticalized gender agreement classes of Indo-European languages. They have a similar semantic basis, and one can develop from the other. They provide a unique insight into how people categorize the world through their language in terms of universal semantic parameters involving humanness, animacy, sex, shape, form, consistency, and functional properties.

Noun categorization devices are morphemes that occur in surface structures under specifiable conditions, and denote some salient perceived or imputed characteristics of the entity to which an associated noun refers (Allan, 1977: 285). They are restricted to classifier constructions, morphosyntactic units (e.g., noun phrases of different kinds, verb phrases, or clauses) that require the presence of a particular kind of morpheme, the choice of which is dictated by the semantic characteristics of the referent of the nominal head of a noun phrase.

Noun categorization devices come in various guises. We distinguish noun classes, noun classifiers, numeral classifiers, classifiers in possessive constructions, and verbal classifiers. Two relatively rare types are locative and deictic classifiers. They share a common semantic core and differ in the morphosyntactic contexts of their use and in their preferred semantic features.

Noun Classes

Some languages have grammatical agreement classes based on such core semantic properties as animacy, sex, and humanness, and sometimes also shape. The number of noun classes (also known as genders, or gender classes) varies – from two, as in Portuguese or French, to 10 or so, as in Bantu, or even to several dozen, as in some languages of South America. Noun classes can to a greater or lesser extent be semantically transparent, and their assignment can be based on semantic, morphological, and/or phonological criteria. They are realized through agreement with a modifier or the predicate outside the noun itself. Examples (1) and (2), from Portuguese, illustrate masculine and feminine genders, which are marked on the noun itself and on the accompanying article and adjective.

(1) o menin-o bonit-o
ARTICLE: MASC.SG child- MASC.SG beautiful- MASC.SG
'the beautiful boy'

(2) a menin-a bonit-a
ARTICLE: FEM.SG child-FEM.SG beautiful-FEM.SG
'the beautiful girl'

The cross-linguistic properties of noun classes are the following:

1. There is a limited, countable number of classes.
2. Each noun in the language belongs to one (or sometimes more than one) class.
3. There is always some semantic basis to the grouping of nouns into gender classes, but languages vary in how much semantic basis there is. This usually includes animacy, humanness and sex, and sometimes also shape and size.
4. Some constituent outside the noun itself must agree in gender with a noun. Agreement can be with other words in the noun phrase (adjectives, numbers, demonstratives, articles, etc.) and/or with the predicate of the clause, or an adverb.

In some languages there is a marker of noun class on every noun; in some languages nouns bear no marker. Noun class systems are typically found in languages with a fusional or agglutinating (not an isolating) profile. Languages often have portmanteau morphemes combining information about noun class with number, person, case, etc.

The semantics of noun classes in the languages of the world involves the following parameters:

- Sex: feminine vs. masculine, as in many Afroasiatic languages, in East-Nilotic, and in Central Khoisan
- Human vs. nonhuman, as in some Dravidian languages of India
- Rational (humans, gods, demons) vs. nonrational, as in Tamil and other Dravidian languages
- Animate vs. inanimate, as in Siouan, from North America

The term neuter is often used to refer to irrational, inanimate gender or to a residue gender with no clear semantic basis.

Languages can combine these parameters. Zande and Ma (Ubangi, Niger-Congo) distinguish masculine, feminine, nonhuman animate, and inanimate. Godoberi (Ghodoberi) (Northeast-Caucasian) has feminine, masculine, and nonrational genders.

Primarily sex-based genders can have additional shape- and size-related meanings. In languages of the Sepik region of New Guinea, feminine is associated with short, wide, and round, and masculine with long, tall, and narrow objects (e.g., Ndu family; Alamblak). Feminine is associated with small size and diminutives in Afroasiatic and East-Nilotic languages; masculine includes long, thick, solid objects. Hollow, round, deep, flat, and thin objects are feminine in Kordofanian and Central Khoisan languages (Heine, 1982: 190–191). Unusually large objects are feminine in Dumo, a Sko language from New Guinea (see the summary in Aikhenvald, 2000: 277).

In some languages, most nouns are assigned to just one noun class; in other languages, different noun classes can be chosen to highlight a particular property of a referent. Manambu, a Ndu language from the Sepik area, has two genders. The masculine gender includes male referents, and feminine gender includes females. But the gender choice depends on other factors and can vary: if the referent is exceptionally long, or large, it is assigned masculine gender; if it is small and round, it is feminine.

Rules for the semantic assignment of noun classes can be more complex. The Australian language Dyirbal (Dixon, 1972: 308–312) has four noun classes. Three are associated with one or more basic concepts: Class I – male humans, nonhuman animates; Class II – female humans, water, fire, fighting; Class III – nonflesh food. Class IV is a residue class covering everything else. There are also two rules for transferring gender membership. By the first, an object can be assigned to a gender by its mythological association rather than by its actual semantics. Birds are classed as feminine by mythological association, since women's souls are believed to enter birds after death. The second transfer rule is that if a subset of a certain group of objects has a particular important property, e.g., being dangerous, it can be assigned to a different class from the other nouns in that group. Most trees without edible parts belong to Class IV, but stinging trees are placed in Class II.

A typical gender system in Australian languages contains four terms that can be broadly labeled as masculine, feminine, vegetable, and residual (Dixon, 2002: 449–514). Andian (Northeast Caucasian) languages have a special noun class for insects, and Bantu languages for places (also see Corbett, 1991).

The degree of semantic motivation for noun classes varies from language to language. Noun classes in Bantu languages constitute an example of a semantically opaque system. Table 1 summarizes a basic semantic grid common to Bantu noun class systems (Spitulnik, 1989: 207) based on the interaction of shape, size, and humanness. However, these parameters provide only a partial semantic motivation for the noun classes in individual Bantu languages. (In the Bantuist tradition, every countable noun is assigned to two classes: one singular and one plural.)

Table 1 Noun classes in Bantu

Class	*Semantics*
1/2	Humans, a few other animates
3/4	Plants, plant parts, foods, nonpaired body parts, miscellaneous
5/6	Fruits, paired body parts, miscellaneous inanimates
7/8	Miscellaneous inanimates
9/10	Animals, miscellaneous inanimates, a few humans
11/10	Long objects, abstract entities, miscellaneous inanimates
12/13	Small objects, birds
6	Masses
14	Abstract qualities, states, masses, collectives
15	Infinitives

In modern Bantu languages, however, noun class assignment is often much less semantically motivated, though the semantic nucleus is still discernible. Thus, in Babungo, Class 1/2 is basically human; however, it is a much bigger class than it was in Proto-Bantu, and also contains many animals, some birds and insects, body parts, plants, and household and other objects, e.g., necklace, pot, book, rainbow (Schaub, 1985: 175). Shape and size also appear as semantic parameters: in ChiBemba, class 7/8 is associated with large size and carries pejorative overtones, while class 12/13 includes small objects and has overtones of endearment (also see Denny, 1976; Aikhenvald, 2000: 281–283).

In a seminal study, Zubin and Köpcke (1986) provided a semantic rationale for the gender assignment of nouns of different semantic groups in German. Masculine and feminine genders mark the terms for male and female adults of each species of domestic and game animals (following the natural sex principle), and neuter is assigned to non-sex-specific generic and juvenile terms. Masculine gender is used for types of cloth, for precipitation and wind, and for minerals. Disciplines and types of knowledge have feminine gender, and games and types of metal – with the exception of alloys – have neuter gender. This is contrary to a common assumption that there is no real semantic basis for gender assignment in the well-known Indo-European languages.

Noun class assignment is typically more opaque for inanimates and for nonhuman animates than for humans and high animates. In the Australian language Bininj Gun-Wok (Evans, 2003: 185–199) masculine class includes male humans, the names of certain malevolent beings mostly associated with

the sky, items associated with painting (a male activity), and also some mammals, some snakes, and some birds and fish. Feminine class includes female humans, and also some reptiles, fish, and birds. Vegetable class includes all terms for nonflesh foods, but also a few bird names. Finally, the neuter, or residue, class is the most semantically heterogenous – it includes items that do not fit into other classes, e.g., most body parts, generic terms for plants, and terms for various inanimate objects.

In Jingulu (Pensalfini, 2003: 159–168) nouns divide into four classes, only some of which are more or less semantically transparent. The vegetable class mostly includes objects that are long, thin, or pointed. This class happens to include most vegetables, as well as body parts such as the colon, penis, and neck; instruments such as spears, fire drills, and barbed wire; natural phenomena such as lightning and rainbows; and roads and trenches. The feminine class includes female humans and higher animates, and also words for axes, the sun, and most smaller songbirds. The semantic content of the remaining two classes, masculine and neuter, is much harder to define: masculine is mostly used for the rest of animates and neuter for the rest of inanimates, except that flat and/or rounded inanimates – such as most trees and eggs, and body parts such as the liver and the brow – are masculine.

Noun Classifiers

Noun classifiers categorize the noun with which they co-occur and are independent of any other element in a noun phrase or in a clause. They are often independent words with generic semantics. Thus, in Yidiny, an Australian language, one would not generally say: 'the girl dug up the yam'; it is more felicitous to include generics and say 'the person girl dug up the vegetable yam' (Dixon, 1982: 185), as in (3). Classifier constructions are in square brackets.

(3) [mayi jimirr] [bama-al
vegetable+ABS yam+ABS CL:PERSON-ERG
yaburu-ŋgu] julaal
girl-ERG dig-PAST
'The person girl dug up the vegetable yam'

Every noun in a language does not necessarily take a noun classifier. And a noun may occur with more than one classifier. In Minangkabau, a Western Austronesian language from Sumatra, different noun classifiers may be used with the same noun to express different meanings, e.g., *batang limau* (CL:TREE lemon) 'lemon-tree', *buah limau* (CL:FRUIT lemon) 'lemon-fruit.' They are similar to derivational-like devices. The choice of a noun classifier is predominantly semantic, based on social status, function, and nature, and also on physical properties, e.g., shape. But in some cases the semantic link between a noun classifier and a noun is not obvious. In most languages of the Daly area in Australia, honey takes the noun classifier for flesh food. The choice of noun classifier in Jacaltec, a Mayan language from Guatemala, is often obscured by extension through perceptual analogy; for instance, ice is assigned to the rock class (see Craig, 1986: 275–276).

Noun classifiers are found in numerous Australian languages, in Western Austronesian languages, in Tai languages, and in Mayan languages (Aikhenvald, 2000). In Yidiny (Australian) (Dixon, 1977: 480 ff.; 1982: 192 ff.), a language with 20 noun classifiers, these are of two kinds:

- *Inherent nature* classifiers divide into humans (*waguja* 'man,' *bunya* 'woman,' and a superordinate *bama* 'person,' as in [3]); fauna (*jarruy* 'bird,' *maŋ gum* 'frog,' *munyimunyi* 'ant'); flora (*jugi* 'tree,' *narra* 'vine'); natural objects (*buri* 'fire,' *walba* 'stone,' *jabu* 'earth'); and artefacts (*gala* 'spear,' *bundu* 'bag,' *baji* 'canoe').
- *Function* classifiers are *minya* 'edible flesh food,' *mayi* 'edible nonflesh food,' *bulmba* 'habitable,' *bana* 'drinkable,' *wirra* 'movable,' *gugu* 'purposeful noise.'

A distinction between flesh and nonflesh food is typical for Australian languages with noun classifiers (Dixon, 2002: 454–459).

Noun classfiers for humans often involve social functions. In Mayan languages of the Kanjobalan branch, as in Jacaltec, humans are classified according to their social status, kinship relation, or age. Mam has classifiers for men and women; for young and old men and women; for old men and women to whom respect is due; and for someone of the same status as the speaker. There is also a classifier for babies, and just one nonhuman classifier. In Australian languages, noun classifiers that refer to social status include such distinctions as initiated man. Murinhpatha (Australian) (Walsh, 1997: 256) has a classifier for Aboriginal people (which also covers human spirits) and another for non-Aboriginal people, which includes all other animates.

Nouns with nonhuman, or inanimate, referents are classified in terms of inherent nature-based properties from the natural domains of human interaction: animals, birds, fish, plants, water, fire, minerals, and artefacts. Individual systems may vary. There is often a general term for birds and fish, as in Minangkabau (Western Austronesian); while Ngan'-gityemerri (Australian) and Akatek (Mayan) have a generic noun classifier for animals. Classifiers in

Murrinh-Patha, from Australia, cover fresh water and associated concepts, flowers and fruits of plants, spears, offensive weapons, fire and things associated with fire, time and space, and speech and language, and there is a residue classifier.

There is usually a noun classifier for culturally important concepts. Mayan languages have a noun classifier for corn, a traditionally important crop, and for domesticated dogs, while Daly languages, in northern Australia, have classifiers for spears, diggings sticks, and spear throwers.

Noun classifiers often have to be distinguished from generic nouns. In Yidiny, a test for what can be used as a classifier is provided by the way interrogative-indefinite pronouns are used: there is one that means 'what generic?' and another meaning 'generic being known, what specific?' Another decisive criterion is how obligatory the classifiers are, and whether it is possible to formulate explicit rules for their omission. Incipient structures superficially similar to noun classifiers can be found in Indo-European languages. In English it is possible to use a proper name together with a descriptive noun phrase, such as *that evil man Adolf Hitler*, but this type of apposition is rather marked and used to achieve rhetorical effect. Lexicosyntactic mechanisms of this kind may well be a historical source of noun categorization devices. Noun classifiers should be distinguished from derivational components in class nouns, such as *berry* in English *strawberry*, *blackberry*, etc., with their limited productivity, high degree of lexicalization, and the fact that they are restricted to a closed subclass of noun roots.

Numeral Classifiers

Numeral classifiers are morphemes that only appear next to a numeral, or a quantifier; they may categorize the referent of a noun in terms of its animacy, shape, and other inherent properties. Uzbek, a Turkic language, has 14 numeral classifiers. A classifier for humans is shown in (4). Inanimate objects are classified by their form, as shown in (5) (Beckwith, 1998).

(4) bir nafar âdam
one CL:HUMAN person
'one person'

(5) bir bâs karâm
one CL:HEAD.SHAPED cabbage
'one (head of) cabbage'

Numeral classifiers are relatively frequent in isolating languages of Southeast Asia; in the agglutinating North Amazonian languages of South America; in Japanese, Korean, and Turkic; and in the fusional Dravidian and Indic languages.

In a language with a large set of numeral classifiers, the way they are used often varies from speaker to speaker, depending on the speaker's social status and competence (Adams, 1989). In this (and in the ways they are acquired by children), they are much more similar to the use of lexical items than to a limited set of noun classes. Each noun in the language does not have to be associated with a numeral classifier. Some nouns take no classifier at all; and some nouns take more than one classifier, depending on which property of the noun's referent is in focus.

Numeral classifiers are always determined by the semantics of the noun referent. Typical semantic parameters are animacy, physical properties (such as dimensionality, shape, consistency, nature), functional properties (e.g., object with a handle), and arrangement (e.g., bunch). There can also be specific classifiers for culturally important items, e.g., canoe, house. A few languages (e.g., Kana, a Cross-River language from Nigeria, and a number of New Guinea languages) (Aikhenvald, 2000: 287–288) have no classifier for animates or humans: when counted, these are classified by shape or by function. For instance, a human is assigned to a class of vertically positioned or elongated objects.

A typical problem with numeral classifiers concerns differentiating between sortal classifiers, which just characterize a referent, and mensural classifiers, which contain information about how the referent is measured. As Ahrens (1994: 204) put it, classifiers can classify only a limited and specific group of nouns, while measure words can be used as a measure for a wide variety of nouns. Almost every language, whether it has numeral classifiers or not, has quantifiers, the choice of which may depend on the semantics of the noun. This often depends on whether the noun referent is countable or not. For instance, in English *much* is used with noncountable nouns, and *many* with countable nouns; other languages have just one word covering 'much' and 'many.' The choice of quantifying expressions may also depend on the properties of the referent noun; for instance, in English we include *head* in *five head of cattle*, *stack* in *three stacks of books*, *flock* in *two flocks of birds*, and so on. These quantifying expressions are not numeral classifiers, because they do not fill an obligatory slot in the numeral-noun construction, but are instead used in a type of construction that is also employed for other purposes. For instance, quantifier constructions in English *three head of cattle* are in fact a subtype of genitive constructions. This is the main reason that English is not a numeral classifier language. The quantifiers also have a lexical meaning of their own.

Classifiers in Possessive Constructions

Classifiers in possessive constructions are of three kinds. *Relational classifiers* categorize the ways in which noun referents relate to, or can be manipulated by, the possessor – whether they are to be eaten, drunk, worn, etc. They tend to occur in languages that distinguish alienable and inalienable possession. In Fijian (Lichtenberk, 1983: 157–158), different classifiers are used to categorize kava as something one is going to drink, as in (6), or as something one has grown or is going to sell, as in (7).

(6) na me-qu yaqona
ARTICLE CL:DRINKABLE-my kava
'my kava (which I intend to drink)'

(7) na no-qu yaqona
ARTICLE CL:GENERAL-my kava
'my kava (that I grew, or that I will sell)'

Oceanic languages typically have from two to five relational classifiers, while Kipeá-Karirí, an extinct Macro-Jê language from Brazil, had 12. Categorization of the possessive relationship via a relational classifier is based on functional interaction between possessor and possessed. The primary semantic division of referents is into consumable and nonconsumable, as in Fijian, or general and alimentary, as in Manam (Lichtenberk, 1983; Dixon, 1988: 136). Consumable objects can be further classified according to the way in which they are consumed (eaten, drunk, chewed), or prepared (e.g., cooked or roasted). Nonconsumable objects are classified according to how they have been acquired (e.g., found, or received as a gift, as in Kipeá-Karirí). Value is a semantic parameter used in relational classifiers in Oceanic languages. Humans can be classified by their social function, that is, social status or kinship relationship, as in Ponapean, a Micronesian language.

Possessed classifiers characterize a possessed noun itself, based on the physical properties (shape, form, consistency, function) or animacy of its referent, as in Panare (a South American language from the Carib family) (Aikhenvald, 2000: 128), shown in (8).

(8) y-uku-n wanë
1sg-CL:LIQUID-GENITIVE honey
'my honey (mixed with water for drinking)'

Possessed classifiers can also be in a generic-specific relationship with the noun they categorize (this is similar to noun classifiers mentioned in this article). In some Carib languages, 'my papaya' can only be phrased as 'my fruit papaya,' as in (9), from Macushí:

(9) u-yekkari ma'pîya
1sg-CL:FRUIT.FOOD papaya
'my papaya'

Table 2 Examples of the use of 'give' in Mescalero Apache

1. *Nát'uhí* **shán'aa** 'Give me (a plug of) tobacco'
2. *Nát'uhí* **shánkaa** 'Give me (a can, box, pack) of tobacco'
3. *Nát'uhí* **shánłtı̨į** 'Give me (a bag) of tobacco'
4. *Nát'uhí* **shántı̨į** 'Give me (a stick) of tobacco'
5. *Nát'uhí* **shánjaash** 'Give me (loose, plural) tobacco'

Generic possessed classifiers are often function-based. Uto-Aztecan languages have possessed classifiers for pets and domesticated plants.

Only one language, Dâw (from the Makú family in South America), has *possessor* classifiers characterizing the possessor in possessive constructions in terms of animacy.

Verbal Classifiers

Also called *verb-incorporated classifiers*, they appear on the verb, categorizing a noun, which is typically in S (intransitive subject) or O (direct object) function, in terms of its animacy, shape, size, structure, and position. Example (10), from Waris, a Papuan language of the Border family (Brown, 1981: 96), shows how the classifier-*put*-'round object' is used with the verb 'get' to characterize its O argument, coconut, as a round object.

(10) sa ka-m put-ra-ho-o
coconut 1sg-to VERBAL.CL:ROUND-get-BENEFACTIVE-IMPERATIVE
'Give me a coconut (literally coconut to-me round.one-give)'

Suppletive (or partly analyzable) classificatory verbs are a subtype of verbal classifiers. Classificatory verbs can categorize the S/O argument in terms of its inherent properties (e.g., animacy, shape, form, and consistency), as in Athapascan languages of North America, such as Mescalero Apache, shown in Table 2. Different arrangements of tobacco are reflected in the form of a classificatory verb whose basic meaning is 'give' (in bold) (Rushforth, 1991):

Alternatively, classificatory existential verbs can categorize the S/O argument in terms of its orientation or stance in space, and also to its inherent properties, as in Dakota and Nevome, from North America, and in Papuan languages of the Engan family in the Highlands of New Guinea. In Enga, a verb meaning 'stand' is used with referents judged to be tall, large, strong, powerful, standing, or supporting, e.g., men, houses, trees; and 'sit' is used with referents judged to be small, squat, horizontal, or weak, e.g., women, possums, ponds.

Cross-linguistically, classificatory verbs tend to belong to the semantic groups of handling, motion, and existence/location. That classificatory verbs should combine reference to inherent properties of referents, and to their orientation, is not surprising. Shape, form, and other inherent properties of objects correlate with their stance in space. Certain positions and states are only applicable for objects of particular kinds; for instance, a tree usually stands, and only liquids can flow. However, classificatory verbs differ from the lexical selection of a verb in terms of physical properties or the position of an object. Most languages have lexical items similar to English *drink* (which implies a liquid O), or *chew* (which implies an O of chewable consistency). Unlike these verbs, classificatory verbs make consistent paradigmatic distinctions in the choice of semantic features for their S/O argument throughout the verbal lexicon. In other words, while English distinguishes liquid and nonliquid objects only for verbs of drinking, classificatory verbs provide a set of paradigmatic oppositions for the choice of verb sets depending on the physical properties of all kinds of S/O. Similarly, posture verbs in many languages tend to occur with objects of a certain shape. For instance, in Russian, long, vertical objects usually stand, and long, horizontal ones lie. However, the correlations between the choice of the verb and the physical properties of the object are not paradigmatic; these verbs cannot be considered classificatory.

Locative Classifiers

Locative classifiers occur with locative prepositions and postpositions, and categorize the head noun in terms of its animacy or physical properties, including form and shape. These are found in South American Indian languages of the Carib family, and in Palikur, an Arawak language from Brazil: e.g., *pi-wan min* (2sg-arm LOC.CL + VERTICAL) 'on your (vertical) arm'; *ah peu* (tree LOC.CL + BRANCH LIKE) 'on (branchlike) tree'.

Deictic Classifiers

Deictic classifiers occur on deictics within a noun phrase and categorize the noun referent in terms of its inherent properties and position in space, such as horizontal or vertical. They are found in Siouan languages from North America, e.g., Mandan *dɛ-mãk* 'this one (lying)'; *dɛ-nak* 'this one (sitting).' Nouns are typically classified by their canonical position, which correlates with their shape and extendedness; for instance, in Pilagá (a Guaicuruan language, from Argentina), fire and stones are classified as horizontal, and buildings and animals as sitting.

All noun categorization devices use the same set of core parameters, which include:

- animacy;
- physical properties covering shape and dimensionality (one-, two-, or three-dimensional objects, including long, flat, and round referents) and direction; size; consistency (flexible, hard or rigid, liquid); material (what the object is made of, e.g., clothlike);
- functional properties (to do with specific uses of objects or kinds of action typically performed on them), including social status, which can be considered a subtype of functional categorization;
- arrangement (that is, configuration of objects, e.g., a coil of rope or a bunch).

Various kinds of noun categorization devices opt for different preferred semantic parameters: animacy and humanness are predominant in noun classes, while noun classifiers often categorize referents in terms of their function and social status. Numeral classifiers typically categorize referents by shape (e.g., round or vertical), while verbal classifiers may also involve orientation (vertical or horizontal). Semantic parameters employed in noun categorization systems follow some tendencies. If a language has classifiers for three-dimensional objects, it is likely to also have classifiers for two-dimensional ones. A summary of preferred semantic parameters depending on a type of noun categorization device is in Table 3 (for their cognitive correlates, see also Bisang, 2002). These preferences represent only tendencies.

Generic-specific relations are characteristic of noun classifiers, verbal classifiers, and sometimes possessed classifiers, but not of other types (they are rare in numeral classifiers).

The semantic complexity of an individual noun class or classifier varies. Some are semantically simple, e.g., the classifier 'person' in Malay and Minangkabau used with all humans. Others undergo semantic extensions, and their choice is less straightforward. Consider the semantic structure of the classifier *-hon* in Japanese (Matsumoto, 1993: 676–681). In its most common use, it covers saliently one-dimensional objects, e.g., long, thin, rigid objects such as sticks, canes, pencils, candles, trees, dead snakes, and dried fish. It also covers martial arts contests with swords (which are long and rigid), hits in baseball, shots in basketball, Judo matches, rolls of tape, telephone calls, radio and TV programs, letters, movies, medical injections, bananas, carrots, pants, guitars, and teeth. This heterogeneity results from various processes of semantic extension and metonymy. Extensions can be based on certain rules for transferring class

Table 3 Preferred semantic parameters in classifiers

Classifier	*Typical semantics*	*Generic-specific relation*
Noun classes	Animacy, humanness, physical properties, rarely nature or function	No
Numeral classifiers	Animacy, humanness, physical properties, nature, rarely functional properties	Rare
Noun classifiers	Social status, functional properties, nature	Yes
Verbal classifiers	Physical properties, rarely animacy, nature	Yes
Relational classifiers	Functional properties	No
Possessed	Physical properties, nature, animacy	Yes
Classifiers	Functional properties	
Locative classifiers	Physical properties, rarely animacy	No
Deictic classifiers	Directionality, physical properties	No

membership, as in Dyirbal (see the section "Noun Classes").

According to these principles, idealized models of the world – for instance, myths and beliefs – can account for other chaining links within the structure of a class. In Dyirbal, birds belong to feminine Class II, because they are believed to be the spirits of dead human females.

A further type of extension is the Domain of Experience Principle, which links members thought to be associated with the same experience domain. Thus, fish in Dyirbal belong to Class 1, since they are animate, and so do fishing implements, because they are associated with the same activity. These domains are often culture-specific, and subject to change with sociocultural changes. The numeral classifier *tay* in Korean was originally used with reference to traditional vehicles, and then was extended to introduced European artifacts with wheels. It was further extended to any electric machinery, and to other kinds of machines or instruments, including even the piano. In Austroasiatic languages, shape parameters in inanimate categorization account for typical semantic extensions of terms for plants and their component parts when employed as classifiers, such as small and roundish (from the word for 'seed'), round (from 'fruit'), bulky (from 'tuber'), flat and sheetlike (from 'flower,' 'leaf,' 'fiber'), and long (from 'stalk,' 'stick,' 'sprout') (Conklin, 1981: 341).

An instructive example of prototype-and-extenson in a multiple classifier system comes from classifier *tua* in Thai (used with numerals, demonstratives, and adjectives). The structure of the category is shown in Figure 1. Arrows indicate extensions from a prototypical member to a less prototypical one (Carpenter, 1987: 45–46).

The prototypical referent classified with *tua* is a four-legged animal, such as a dog or a water buffalo. The classifier extends to include trousers and shirts, due to their shape: trousers are leglike, and shirts have armlike sleeves. Because of shared function, and the bodylike shape, this classifier also applies to jackets

Figure 1 Structure of the *tua* category in Thai.

and skirts and even to dresses, underwear, and bathing suits. The general four-legged shape of items of furniture, such as tables and chairs, accounts for their inclusion in the category covered by the classifier *tua*. Other kinds of furniture were then added because of their shared function with tables and chairs. 'Letter (of the alphabet)' in Thai is a compound *tua nangseu* 'body book', so a combination of shape and repetition of the generic compound head caused letters to be classified with *tua*. Numbers were included either on the basis of shape or by their shared function with letters. Ghosts were included because of their similarity with the two-limbed shape of a human body. Semantic extensions of classifiers can be manipulated by language planners. Following an order of King Mongkut issued in 1854, 'noble' animals, such as elephants and horses, should be counted without any classifier; the classifier *tua* could be used only for animals of a 'lower' status. In Setswana, a Bantu language with a large set of noun classes, it is now considered politically incorrect to refer to ethnic minorities, such as the Chinese or the Bushmen, using noun class 5/6 (which includes substances, such as dirt or clay, and abstract nouns); all humans have to be referred to with the 'human' class 1/2 (see Table 1).

Noun categorization devices are hardly ever semantically redundant. They are often used to distinguish what can be encoded with different lexemes in some languages. For instance, in Burmese a river can be viewed as a place, as a line (on a map), as a section, as a sacred object, or as a connection. These meanings are distinguished through the use of different

Table 4 Categorization of an inanimate noun in Burmese with a classifier

Noun	*Numeral*	*Classifier*	*Translation*
miyiʔ	tə	yaʔ	river one place (e.g., destination for a picnic)
miyiʔ	tə	tan	river one line (e.g., on a map)
miyiʔ	tə	hmwa	river one section (e.g., a fishing area)
miyiʔ	tə	sin	river one distant arc (e.g., a path to the sea)
miyiʔ	tə	θwɛ	river one connection (e.g., connecting two villages)
miyiʔ	tə	pa	river one sacred object (e.g., in mythology)
miyiʔ	tə	khu	river one conceptual unit (e.g., in a discussion of rivers in general)
miyiʔ	tə	miyiʔ	river one river (the unmarked case)

numeral classifiers – this is shown in Table 4 (Becker, 1975: 113).

In Apache, a plug, a box, a stick, and a bag of tobacco are distinguished through the use of different classificatory verbs. In languages with overt noun class marking, variability in marking noun class on the same root is a way of creating new words. In Bantu languages, such as Swahili, most stems usually occur with a prefix of one class. Prefixes can be substituted to mark a characteristic of an object. *M-zee* means 'old person' and has the human class prefix *m-*. It can be replaced by *ki-*(inanimate class) to yield *ki-zee* 'scruffy old person'. In Dyirbal, the word 'man' can be used with the feminine class marker, instead of masculine, to point out the female characteristics of a hermaphrodite. In Manambu, 'head' is usually feminine because of its round shape, but it is treated as masculine when a person has a headache, since then the head feels heavy and unusually big.

We have seen that semantically noun categorization devices are heterogenous, nonhierarchically organized systems that employ both universal and culture-specific parameters. The ways these parameters work are conditioned and restricted by cognitive mechanisms and the sociocultural environment. Among universal parameters are animacy, humanness, and physical properties, e.g., shape, dimensionality, consistency. Culture-specific parameters can cover certain functional properties and social organization.

Classificatory parameters associated with function rather than physical properties are more sensitive to cultural and other nonlinguistic factors. Human categorization, as a sort of 'social' function, depends entirely on social structure. Functional categorization of inanimate and nonhuman objects is directly related to cultural notions. Animacy and sex, when extended metaphorically, are influenced by social stereotypes and beliefs.

Correlations between the choice of physical properties encoded in classifiers and nonlinguistic parameters are much less obvious. They may relate to the cultural salience of certain shapes or forms, and they may ultimately be based on typical metaphorical extensions.

Classroom Talk

E Hinkel, Seattle University, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

Much classroom activity takes the form of talk. In recent decades, studies of teacher and student spoken language in the classroom have been undertaken from a variety of perspectives in applied linguistics, education, ethnography, and ethnomethodology. In particular, the analyses of talk between the teacher and the students, as well as among students, seek to understand how the spoken language and the discourse of the classroom affect learning (including language learning) and the development of sociocultural affiliation and identity (e.g., Watson-Gegeo, 1997).

To a great extent, spoken language and face-to-face interaction constitute the foundational aspects of both teaching and learning at school. Although specialists in education and teaching first became interested in the impact of classroom discourse and interaction on students' learning and the development of cognitive skills in the 1930s and 1940s, since that time, research on classroom talk has moved forward in a number of directions. In the study of language and applied linguistics, classroom talk has been the subject of considerable exploration in discourse, conversation, and text analyses, as well as sociolinguistic and sociocultural features of interaction.

The linguistic features of classroom talk were studied intensively in the 1970s and 1980s, when the uses of language and forms of interaction at school became an important venue in discourse, pragmatic, and literacy studies. Many of the early discourse analyses focused on the linguistic features of talk, narrative structure, common speech acts, their sequences, and the contexts in which they occurred, as well as the flow of classroom speech (e.g., Sinclair and Coulthard, 1975; Stubbs, 1983). As a matter of course, these studies approached classroom talk as occurrences of conversational discourse, without attempting to discern the effect of the language spoken in the classroom on student learning and the educational processes. The analyses of the discourse flow and the language of interaction revealed that classroom talk is highly structured and routinized.

Building on the discourse-analytic foundation, the influential work of such sociolinguists and cognitive linguists as Cazden (2001), Gumperz (1982, 1986), Edwards and Mercer (1987), and Edwards and Westgate (1994) employed a combination of methodological perspectives in their explorations of the spoken discourse, language, and the structure of interaction in schooling. In general terms, sociolinguistics takes into account the social contexts and the structure of interaction to determine how they shape the spoken language. Sociolinguistic research methods in the classroom are usually complemented by ethnographic and pragmatic perspectives. Taken together, the findings of these studies have brought to the foreground issues of power, socioeconomic class, culture, and the social construction of experience in

Classroom Talk

E Hinkel, Seattle University, Seattle, WA, USA

Much classroom activity takes the form of talk. In recent decades, studies of teacher and student spoken language in the classroom have been undertaken from a variety of perspectives in applied linguistics, education, ethnography, and ethnomethodology. In particular, the analyses of talk between the teacher and the students, as well as among students, seek to understand how the spoken language and the discourse of the classroom affect learning (including language learning) and the development of sociocultural affiliation and identity (e.g., Watson-Gegeo, 1997).

To a great extent, spoken language and face-to-face interaction constitute the foundational aspects of both teaching and learning at school. Although specialists in education and teaching first became interested in the impact of classroom discourse and interaction on students' learning and the development of cognitive skills in the 1930s and 1940s, since that time, research on classroom talk has moved forward in a number of directions. In the study of language and applied linguistics, classroom talk has been the subject of considerable exploration in discourse, conversation, and text analyses, as well as sociolinguistic and sociocultural features of interaction.

The linguistic features of classroom talk were studied intensively in the 1970s and 1980s, when the uses of language and forms of interaction at school became an important venue in discourse, pragmatic, and literacy studies. Many of the early discourse analyses focused on the linguistic features of talk, narrative structure, common speech acts, their sequences, and the contexts in which they occurred, as well as the flow of classroom speech (e.g., Sinclair and Coulthard, 1975; Stubbs, 1983). As a matter of course, these studies approached classroom talk as occurrences of conversational discourse, without attempting to discern the effect of the language spoken in the classroom on student learning and the educational processes. The analyses of the discourse flow and the language of interaction revealed that classroom talk is highly structured and routinized.

Building on the discourse-analytic foundation, the influential work of such sociolinguists and cognitive linguists as Cazden (2001), Gumperz (1982, 1986), Edwards and Mercer (1987), and Edwards and Westgate (1994) employed a combination of methodological perspectives in their explorations of the spoken discourse, language, and the structure of interaction in schooling. In general terms, sociolinguistics takes into account the social contexts and the structure of interaction to determine how they shape the spoken language. Sociolinguistic research methods in the classroom are usually complemented by ethnographic and pragmatic perspectives. Taken together, the findings of these studies have brought to the foreground issues of power, socioeconomic class, culture, and the social construction of experience in

the classroom. Many, if not most, of these investigations point to the common and frequent mismatches between the normative properties of the school language and the language used in students' families.

A number of important and congruent findings have emerged from the study of classroom discourse and spoken language. One prominent thread in research is that a large majority of classroom interactions occur between the teacher and the students, individually or in groups, although some student–student interactions also take place during group or collaborative activities. Investigations carried out in different locations and countries around the world have shown that in classroom interactions, teachers talk approximately 75% of the time, with the remainder divided among the students. This pattern of talk seems to be comparatively consistent and, on the whole, resistant to change, despite the calls for its modification or attempted educational reforms (e.g., van Lier, 1988, 1996; Dysthe, 1996; Nystrand, 1997).

Another strand that runs through practically all studies is that classroom talk includes a number of predictable and observable sequences. Much of the classroom spoken language centers around knowledge and information elicitation turns between the teacher and the students, cohesive topical stretches of talk, or exchanges motivated by instructional activity in the classroom. In general terms, teacher–student exchanges reflect the unequal and hierarchical relationship of their participants in teacher-fronted classrooms (Edwards and Westgate, 1994).

The typical conversational patterns in such dyadic exchanges proceed along the lines of what has become known as Initiation-Response-Feedback (IRF) (also called Initiation-Response-Evaluation or Question-Answer-Comment), e.g.:

Teacher: So, why did Peter run to the village?
Student: For a joke.
Teacher: Right!

In such routine classroom sequences, the teacher initiates the interaction or asks a question, the student responds or answers the question, and the teacher takes the concluding turn that provides a commentary (e.g., *So, Peter was bored*) or an evaluation (e.g., *Good/Great answer*).

Spoken language in the classroom is fundamentally different from many other types of talk, such as conversations among peers, coworkers, or family members. Some researchers, such as, for example, Mehan (1979) and van Lier (1996), have pointed out that IRF interactions are, by their nature, artificial and constrained and, for this reason, they cannot be analyzed as ordinary conversational discourse that follows ordinary interactional conventions. In their view, the institutionalized structure of classroom talk is crucially distinct when the teacher nominates topics and speakers, and controls turn-taking and the amount of participant talk.

The decades of investigating talk in the classroom have also identified the social, cultural, and behavioral practices that predominate in classroom discourse. Numerous studies carried out in such locations as the United States, the United Kingdom, and Scandinavia have demonstrated that complex systems of sociocultural prescriptions and expectations that exist in the wider society are strongly reflected in the norms of speaking and behaving in the classroom. Influential works by, for example, Heath (1983) and Gee (1990), highlight the pervasive discontinuities between the middle-class linguistic and interactional practices widely adopted in schooling and those in children's homes. The disparities between the rigidly prescribed and traditional rules of the classroom talk extend to the learning, socialization, and literacy development of the children in racially and linguistically diverse schools. Examples of language and interaction mismatches abound (e.g., Scollon and Scollon, 1981; Brock *et al.*, 1998):

- Spanish-speaking students in the United States are not always familiar with the predominant norms of classroom behavior when students are expected to be quiet while the teacher or another student is speaking.
- Native American students often participate in class conversations collectively, but not individually, as is usually expected in U.S. and Canadian schools.
- Ethnic Chinese students in U.K. and Australian schools rarely speak during requisite classroom activities and strongly prefer to work alone instead of working in groups, where much conversation is required.

In all, a large number of sociolinguistic and ethnographic studies have shown conclusively that the practice of classroom talk and the rigid norms of interaction in schooling represent culturally bound contexts for learning. As an outcome, the learning and literacy development of racial and linguistic minority students can be constrained in the classrooms where the structure of talk and discourse follows sociocultural prescriptions different from those in the students' communities outside the school.

From a different vantage point, research in discourse and conversation analysis, as well as language acquisition, has also shown that classroom talk has numerous important learning, cognitive, and social functions. The most common of these include exposure to language and linguistic input in the form

of, for example, direct instruction, questions and answers, orientations to topics, information elicitations, explanations, hypothesis-making, and using evidence. In the following example of a story-circle discussion, the teacher attempts to elicit more elaborate explanations and evidential support for the students' in effect accurate appraisal of the story events:

Teacher: Ok, so Laura got a pretty new dress ... . A very nice dress. She must have liked it. So, did she like it?
Several students together: Noooooooo.
Teacher: She didn't? Well, no, she didn't ... . Eh, ok, ... so how do we know that she didn't?
Sam: She said ... I ... I don't need it ... it ... the new one. So, she didn't.
Teacher: Good job, Sam, good thinking ... . Laura **really** didn't need this dress? Ok, or maybe, she didn't like it? Can we tell? How can we tell?

In addition to guiding the students to support their conclusion by means of the information in the story, the teacher also uses relatively advanced syntactic constructions, such as *must have liked it* and a number of complex sentences with noun clauses and negation.

More recently, with the increased understanding of learners' cognitive and linguistic development, investigations of classroom talk have continued to gain importance in language teaching and education of second language and minority students. In many cases, discourse and conversation analyses of classroom talk have also shown that language uses and interactions in educational contexts play an important role in learner language and cognitive development (see, e.g., Edwards and Westgate, 1994; Dysthe, 1996; Seedhouse, 2004). For instance, the uses of lexical and grammatical features in classroom talk have allowed researchers to assess the value of classroom language exposure and input in language learning and the growth of first and second language literacy skills.

Among other venues, for example, the uses of display and referential questions in classroom talk have been extensively researched. The purpose of display questions is to elicit information already known to the interaction participant, who asks the question to lead to the display of knowledge or familiarity with information, e.g., "What do we call this thing?" On the other hand, referential questions elicit information that is not known to the speaker, e.g., "Why did you and Mary put this picture before that one?" Studies of referential questions have shown that their educational uses lead to different classroom exchanges that result in significantly longer speech events, higher rates of lexically and syntactically complex responses, and greater opportunities for learner language use (e.g., Edwards and Mercer, 1987; van Lier, 1996).

In-depth investigations of classroom talk have undertaken to gain insight into a large number of sociocultural and linguistic properties of interaction, such as equal and unequal power relationships, some aspects of turn-taking, talk management, and the timing and length of speech events (e.g., Markee, 2000). From the perspective of conversation analysis, classroom interactions have provided a fertile ground for examinations of repair, correction, self-correction, discourse, and face-saving markers in equal and unequal power educational contexts.

At present, sociologists, educators, and linguists almost universally recognize that social and cultural institutions of schooling are inseparable from how language and discourse are employed to transmit knowledge and socialize learners (e.g., Watson-Gegeo, 1997; Cazden, 2001).

Clause Relations

M Hoey, University of Liverpool, Liverpool, UK

© 2006 Elsevier Ltd. All rights reserved.

The concept of the 'clause relation' grew up in a number of places at the same time at the end of the 1960s and at the beginning of the 1970s. Given that there was limited contact between the linguists responsible for the notion, it is unsurprising that each linguist or group of linguists labeled and defined it slightly differently, but a basic shared element in the definitions was that a clause relation was a regularly recurring semantic relationship holding between parts of a text, minimally clauses, that helped account for the organization of the text.

One of the places where the concept of the clause relation was developed was at Hatfield Polytechnic, Hatfield, England, where Eugene Winter headed a small group of researchers interested in the ways in which written text may be organized. Winter had worked with M. A. K. Halliday, Richard Hudson, Rodney Huddleston, and Alec Henrici on a corpus-based study of scientific writing, funded by the Office of Scientific and Technical Information and completed in 1968, and it had become apparent to him that some aspects of the ways clauses and sentences interconnected in scientific text could not be explained in terms of the scale-and-category model (an early version of systemic grammar) which they were using. He therefore posited that clauses were systematically related to each other (Huddleston *et al.*, 1968; Winter, 1971) in ways that could be described independently of the grammar (though he was always insistent on the close relationship between grammar and clause relations, and felt that grammars needed to be adapted to take account of this relationship). He defined clause relations as follows:

> A clause relation is the cognitive process whereby we interpret the meaning of a sentence or group of sentences in the light of its adjoining sentence or group of sentences. (Winter, 1971 and elsewhere)

It will be noted that, despite its label, a clause relation may hold between sentences and groups of clauses as well as, of course, between clauses. It will also be noted that the definition treats the clause relation as a property of the reader's processing of the text rather than a property of the text itself, an important difference from the position adopted by others working with the notion. These points will be returned to later.

Winter quickly moved to the position that there are two basic kinds of clause relation (Winter, 1971 *et seq.*): matching relations and logical sequence relations (relabeled sequence relations in Hoey, 1983, in order to accommodate spatial and temporal sequence relationships). Matching relations are characterized by two clauses or groups of clauses being matched for points of similarity and difference in the content. Such relations include compatibility (e.g., *I like Mozart and so does my wife*), contrast (e.g., *I like Mozart but my wife does not*), generalization – exemplification (e.g., *My wife doesn't like classical music. For example, she hates Mozart*), and preview–detail (e.g., *There are three composers I especially like. I really enjoy Mozart, I love Bach and I adore Sibelius*) The simplest kind of matching relation is topic maintenance (e.g., *Mozart is one of my favorite composers. He was born in Salzburg*).

Authentic examples of matching relations can be found in the following passage from a 1907 biology primer (*A primer of biology and nature study* by Randal Mundy):

> 2.1 **A Simple Classification of Plants.** – Plants may be divided into two great groups:

Clause Relations

M Hoey, University of Liverpool, Liverpool, UK

© 2006 Elsevier Ltd. All rights reserved.

The concept of the 'clause relation' grew up in a number of places at the same time at the end of the 1960s and at the beginning of the 1970s. Given that there was limited contact between the linguists responsible for the notion, it is unsurprising that each linguist or group of linguists labeled and defined it slightly differently, but a basic shared element in the definitions was that a clause relation was a regularly recurring semantic relationship holding between parts of a text, minimally clauses, that helped account for the organization of the text.

One of the places where the concept of the clause relation was developed was at Hatfield Polytechnic, Hatfield, England, where Eugene Winter headed a small group of researchers interested in the ways in which written text may be organized. Winter had worked with M. A. K. Halliday, Richard Hudson, Rodney Huddleston, and Alec Henrici on a corpus-based study of scientific writing, funded by the Office of Scientific and Technical Information and completed in 1968, and it had become apparent to him that some aspects of the ways clauses and sentences interconnected in scientific text could not be explained in terms of the scale-and-category model (an early version of systemic grammar) which they were using. He therefore posited that clauses were systematically related to each other (Huddleston *et al.*, 1968; Winter, 1971) in ways that could be described independently of the grammar (though he was always insistent on the close relationship between grammar and clause relations, and felt that grammars needed to be adapted to take account of this relationship). He defined clause relations as follows:

> A clause relation is the cognitive process whereby we interpret the meaning of a sentence or group of sentences in the light of its adjoining sentence or group of sentences. (Winter, 1971 and elsewhere)

It will be noted that, despite its label, a clause relation may hold between sentences and groups of clauses as well as, of course, between clauses. It will also be noted that the definition treats the clause relation as a property of the reader's processing of the text rather than a property of the text itself, an important difference from the position adopted by others working with the notion. These points will be returned to later.

Winter quickly moved to the position that there are two basic kinds of clause relation (Winter, 1971 *et seq.*): matching relations and logical sequence relations (relabeled sequence relations in Hoey, 1983, in order to accommodate spatial and temporal sequence relationships). Matching relations are characterized by two clauses or groups of clauses being matched for points of similarity and difference in the content. Such relations include compatibility (e.g., *I like Mozart and so does my wife*), contrast (e.g., *I like Mozart but my wife does not*), generalization – exemplification (e.g., *My wife doesn't like classical music. For example, she hates Mozart*), and preview–detail (e.g., *There are three composers I especially like. I really enjoy Mozart, I love Bach and I adore Sibelius*) The simplest kind of matching relation is topic maintenance (e.g., *Mozart is one of my favorite composers. He was born in Salzburg*).

Authentic examples of matching relations can be found in the following passage from a 1907 biology primer (*A primer of biology and nature study* by Randal Mundy):

> 2.1 **A Simple Classification of Plants.** – Plants may be divided into two great groups:

BRYOPHYTES	or moss-like plants	consist of	a stem and leaves	(but) have no true roots or fibro-vascular bundles
PTERIDOPHYTES	or fern-like plants	possess	stem, leaves	roots and fibro-vascular bundles
replacement (of name)	replacement (of point of comparison)	repetition (by rough paraphrase in this context)	repetition (by use of same words)	replacement (of negative by positive)

Figure 1 A simple analysis of the repetition/replacement pattern in a contrast relation between two pieces of text.

I. *Flowerless Plants* (Cryptogams).
II. *Flowering Plants* (Phanerogams).
I. **Flowerless Plants** comprise the Thallophytes, Bryophytes and Pteridophytes.
  1. THALLOPHYTES have a body commonly in the form of a flattened shoot, termed a thallus. They have no true roots and are reproduced by **spores**. They are thus sub-divided:-
    (a) *Algae*, *e.g.*, sea-weeds and many fresh water plants, such as Chara.
    (b) *Funghi*, *e.g.*, moulds and mushrooms. No chlorophyll is present.
    (c) *Lichens*, peculiar plants each consisting of an alga and a fungus, living together for their mutual advantage.
  2. BRYOPHYTES or moss-like plants consist of a stem and leaves, but have no true roots or fibro-vascular bundles. They are reproduced by **spores**. Bryophytes are sub-divided into:-
    (a) *Hepatics* or *Liverworts*, *e.g.*, Marchantia and Jungermannia.
    (b) *Mosses*. *(See Chapter XXII)*
  3. PTERIDOPHYTES or fern-like plants possess stem, leaves, roots and fibro-vascular bundles, and are reproduced by **spores**. They comprise :-
    (a) *Ferns*.
    (b) *Equisetums* (Horsetails).
    (c) *Lycopodiums* (Club mosses).
II. **Flowering Plants** have root, stem, leaves, flowers and fibro-vascular bundles, and are reproduced by **seed**. They are sub-divided into:-
  (a) GYMNOSPERMS, with seeds naked, *i.e.*, not enclosed in a cavity (ovary); *e.g.*, Cycads, and Conifers such as the pine, fir and yew.
  (b) ANGIOSPERMS, with seeds enclosed in an ovary. They comprise:-
    i. *Monocotyledons* (one seed-leaf or lobe), *e.g.*, grasses, rushes, palms and lilies.
    ii. *Dicotyledons* (two seed-lobes), *e.g.*, most trees, shrubs and herbs.

This passage is more or less entirely made up of different kinds of Matching relations. At the uppermost level, the whole passage is organized by a preview-detail relation, with

> 2.1 A Simple Classification of Plants. – Plants may be divided into two great groups:- I Flowerless Plants (Cryptogams). II Flowering Plants (Phanerogams)

functioning as the preview and the remainder of the passage serving as the detail. Within the paragraphs there are also instances of generalization–example, such as:

> Algae, e.g., sea-weeds and many fresh water plants, such as Chara.

In this case neither the generalization nor the examples are expressed as full clauses. The contrast relation can be illustrated in the following two pieces of text:

> BRYOPHYTES or moss-like plants consist of a stem and leaves, but have no true roots or fibro-vascular bundles.

> PTERIDOPHYTES or fern-like plants possess stem, leaves, roots and fibro-vascular bundles . . .

Winter (1979) noted that pieces of text such as these can be analyzed in terms of what is repeated and what is replaced (see Figure 1). The focus here is on what is replaced rather than on what is repeated, because it is the differences that provide the basis for the classification. In the two pieces of text in Figure 2, however, the focus is on the sameness; this, then, is an instance of a compatibility relation, and it will be seen that the only replacement here is of the topic.

Clause relations may function between large chunks of text (the preview–detail relation) or between bits of clauses (the generalization–example relation) or between one or more clauses (the contrast and compatibility relations). In this respect, the name is misleading, implying as it does that the relationships are only or primarily between clauses. Relations may be inferred by the reader or can be signaled by

They [ref. THALLOPHYTES]	have no true roots and	are reproduced by **spores.**
[ellipsis of BRYOPHYTES]	have no true roots ...	They are reproduced by **spores.**
replacement of name	repetition	repetition

Figure 2 A simple analysis of the repetition/replacement pattern in a compatibility relation between two pieces of text.

the writer, either by parallel structures and repetition as in the compatibility example or by a special vocabulary of signals (signals in the passage include *subdivided*, *e.g.*, *thus*, *but*, *comprise*, *consist of*, *i.e.*, *such as*), which serve to label both prospectively and retrospectively the relations the writer sees between the chunks of text, as well as by typographical features such as listing and capitalization.

As noted above, the other great class of clause relations, according to Winter, is that of the sequence relations. Sequence relations include time sequence (e.g., *she washed her face and then put her coat on*), cause–effect (e.g., *it was cold, so she put her coat on*), instrument–purpose (e.g., *she put her coat on to protect herself from the cold*), instrument–achievement (e.g., *she put her coat on and protected herself against the cold*), and spatial sequence (e.g., *Her coat hung on a clothes-stand in the hall. An old umbrella lay on a table next to it*). It will be noticed from the fabricated examples that, as with the matching relations, the relationship may be between clauses that are syntactically integrated, between clauses that are loosely coordinated or between self-standing sentences. Some of the sequence relations are illustrated in the following extract from a biography of Shakespeare published in 1908 (*A life of William Shakespeare* by Sidney Lee).

> At the beginning of 1616 Shakespeare's health was failing. He directed Francis Collins, a solicitor of Warwick, to draft his will, but, though it was prepared for signature on January 25, it was for the time laid aside. On February 10, 1616, Shakespeare's younger daughter, Judith, married, at Stratford parish church, Thomas Quiney, four years her junior, a son of an old friend of the poet. The ceremony took place apparently without public asking of the banns and before a license was procured. The irregularity led to the summons of the bride and bridegroom to the ecclesiastical court at Worcester and the imposition of a fine.

This passage contains a number of sequence relations. First, we can identify a cause–effect (or cause–consequence) relation between the first sentence and the first clause of the second. Likewise we can see a time sequence relation between the second and third sentence, and another between the third sentence, summarized in the first clause of the fourth (*the ceremony took place*), and the final clause of the fourth (*a license was procured*). The fourth sentence, summarized as the noun phrase *the irregularity*, is the cause and *the summons . . . to the ecclesiastical court* and *the imposition of a fine* are its effects (or consequences), themselves in a time sequence relation. As before, relations may be inferred by the reader or can be signaled by the writer; the special vocabulary of signals used in this passage comprises *before* and *led to*, as well as the use of dates in the second and third sentences.

Winter's work was picked up and developed by a number of linguists, including Winifred Crombie (see below), Michael Hoey, and Michael Jordan (1983, 1985, 1988, 1990, 1992); Jordan's work seeks to integrate clause relational theory with cohesive analysis in interesting ways. Although Winter himself never attempted to itemize or classify clause relations (indeed, in his later work such as Winter, 1982, 1986, 1992, and 1994 he retreated from classificatory systems), they quickly turned into a classificatory system, and here the second place where the idea turned up was influential. Working in conjunction with the Summer Institute of Linguistics, John Beekman and John and Katherine Callow were involved in efforts to translate the Bible into languages in which it had hitherto been unknown. They found that translations that only concerned themselves with the transference of sentence meanings from one language to the other resulted often in stilted and even unintelligible translations. Only if a textual dimension was built in was there a chance of a translation being accepted in the community for which it was intended. More specifically, they argued in a series of articles (Beekman, 1970a, etc.) and a book (Beekman and Callow, 1974) that texts are organized in terms of regular semantic relations the world over and that the first step in undertaking any translation is to analyze the source text into its component relations; the translation may need to configure these relations differently in accordance with the expectations of the target language community but the relations themselves would not be altered. A similar position was argued by Robert Longacre and his colleagues in a range of papers and books (Ballard *et al.*, 1971; Longacre, 1972, 1976 [substantially revised as Longacre, 1983], 1979, *et seq.*), though the

attention in the earlier of these works was on the relationship of clauses only.

The Callows (Callow and Callow, 1992: 6) emphasized the perspective of the writer or speaker rather than that of the reader or listener (in contrast to Winter, see above): "The speaker is central." My own adaptation of Winter's definition (Hoey, 1983) also foregrounded the writer/speaker, though not at the expense of the reader/listener.

Despite the sender/receiver focus of both these perspectives, the practice of clause relation analysts in both the United States and the United Kingdom was message centered. Beekman and the Callows argued that messages are structured. For them, the largest unit of communication is the message, roughly equivalent to the text, and the smallest unit is the proposition, roughly equivalent to the content of a clause. A message consists of 'units-in-relation' and their term for the relation holding between units is 'coherence relation':

> Related propositions constitute a configuration. The clauses *Mary blushed* and *Simon laughed* do not, as they stand, realize a configuration, because their relationship is not clear. But *Mary blushed because Simon laughed* does realize a configuration. *When Mary blushed Simon laughed* realizes a different configuration: the units are the same but the coherence relation is different. (Callow and Callow, 1992: 9)

This analysis is, it will be noted, text centered. The writer is only here in the connectives that make the configuration interpretable. The reader is nowhere. Despite the fact that Beekman and the Callows appear to be talking about the same things as Winter, their starting point was at the other end of the interaction, which is unsurprising, given that their background was in translation. The terms and concepts, though, are very similar. They did not divide relations into matching and sequence relations, but they did have relations such as purpose, reason, result, and identification and they showed how such relations can account for the organization of one of the shorter Epistles, that of Jude (Beekman, 1970b).

Like Beekman and the Callows, Winifred Crombie (1985a, 1985b) had a practical goal – the improvement of ELT materials. Drawing on Winter's work, with a knowledge also of the work of Beekman and his colleagues, she provided one of the fullest classifications of clause relations, which she termed 'semantic relations.' She grouped these relations in a more complex way than Winter or Hoey, her broad categories being temporal, matching, cause–effect, truth and validity, alternation, bonding, paraphrase, amplification, and setting/conduct. It would go beyond the scope of an article such as this to give details of all of these, but bonding, for example, subdivides into:

1. Coupling (two or more juxtaposed members, without comparison or sequence being in focus, e.g., *Achilles wore a robe and carried a shield*)
2. Contrast
3. Statement–exemplification
4. Statement–exception.

Crombie's categories are perceptive and thorough and as a starting point for analysis they comprise the best classification within the British tradition (and arguably elsewhere as well). They are, however, even more text centered than those of Beekman and the Callows, and Crombie sought to represent them formally in quasi-logical and partly abstract fashion. Winter's focus on the reader is not lost, though – she introduced the notion of semantic relations in terms of the questions that might be asked by a reader to elicit particular relations – and she also picked up from Winter an attention to the way relations are signaled, a facet of clause relation analysis that will be returned to later in the article.

Crombie is not the only linguist to have attempted to classify clause relations, though she is probably the only one to have linked such a classification to the ways in which writers may signal to the reader the semantic relations they intend between pieces of text. One pair of linguists who went further down the classificatory road and at the same time further from the interactive starting point is William Mann and Sandra Thompson (1986, 1987; Mann *et al.*, 1992), whose rhetorical structure theory (RST) grew explicitly out of the work of Winter, Jordan (1984), Hoey, and Beekman and the Callows. Like Crombie, Mann and Thompson took great care to formalize and categorize relations and in common with all the linguists so far mentioned, they were driven by a practical goal, in this case the automatic generation of text as well as the automatic processing of text within a systemic-functional tradition.

One of the major features of Mann and Thompson's adaptation of clause relations is that relations are typically asymmetric, with one member being central (the nucleus) and the other being more marginal (the satellite). The relation operates between spans of text and within spans of text. White's (1998) account of the orbital structure of newspaper texts would at first sight be supportive of their position, in that he argued that news stories are organized in terms of a series of satellites all relating back to an initial sentence or sentences that report the core news. White's analysis was not, however, apparently compatible with RST in another respect, as will be explained below.

Mann and Thompson, with Matthiessen, argued for a hierarchical analysis of texts:

> Texts are organized such that elementary parts are composed into larger parts, which in turn are composed into yet larger parts up to the scale of the whole text. (Mann *et al.*, 1992)

This assumption, which they noted is not the only possible assumption one might make, is helpful because it reminds us that chunks of text may relate to other chunks. It also forces a fuller and more systematic examination of the relations in a text. A hierarchical view of clause relations is present also in the work of Gottfried Graustein and Wolfgang Thiele (1981, 1987, etc.), East German linguists who independently developed the notion of configurations of clause relations but were apparently unknown in the American tradition, though in contact from the late 1970s with Winter and his colleagues. Like Mann and Thompson, Graustein and Thiele saw text as hierarchically organized, but they made greater, and more clearly separate, use than Mann and Thompson of culturally popular patterns such as the problem–solution pattern (*see* **Problem-Solution Patterns**).

To show the way a hierarchical analysis can work (though without representing it in accordance with the terms and diagrammatic style of either Mann and Thompson or Graustein and Thiele), it is worth considering again the biology extract we analyzed earlier, which, though it has an apparently straightforward hierarchical organization, permits demonstration of the problems that a strict hierarchical view of the organization of text brings.

The first division into flowerless and flowering plants seems to license a first analysis into two blocks, the first block corresponding to the account of the flowerless plants, i.e., the thallophytes, bryophytes, and pteridophytes, and the second of course the account of the flowering plants (see Figure 3).

What Figure 3 claims is that the passage is divisible into two uneven chunks, the first comprising a general overview of the topic (the preview), the second the particulars of the topic (the details); Winter would have labeled this relation the general–particular relation. The details in turn are divisible into two (again uneven) chunks in a matching contrast relation between the three chunks of text concerned with the description of thallophytes, bryophytes, and pteridophytes and the block of text concerned with the description of flowering plants. As already intimated, the first chunk is further divisible into three subsections relating to three types of flowerless plants, in which the focus is equally on what they share (their compatibility) and where they differ (contrast). Each of these subsections is analyzable on similar lines until all the clauses are accounted for.

All these relations are justifiable in terms of the signals that the writer has incorporated into his text. The initial division into preview and details is established by the repetition of the headings with their Roman numerals and typographical distinctiveness. The contrast is explicitly signaled in advance by the word *divided* and the phrase *two great groups*, and also in the chunks themselves by two parallel questions being answered: what subclasses of flowerless/flowering plants are there, and how do they reproduce? The compatibility relations amongst the three sections on the flowerless plants are signaled by the kinds of repetition patterning that were being illustrated earlier. In short, such an analysis works and indicates both the way a text may be hierarchically organized and the way in which relations may occur between blocks of language.

The problem that the strictly hierarchical position has is that Figure 3 does not reflect all the relations in the text. While the flowering plants section undoubtedly stands in a contrast relation with the preceding three flowerless plants sections, it is also stands in a separate relation of compatibility with the last of the three flowerless plants sections, the pteridophytes. This can be shown in a similar fashion as previously in Figure 4.

The relations of compatibility and contrast in Figure 4 are no different from those we find between the sections devoted to the thallophytes and bryophytes, and indeed it would be possible to argue on linguistic evidence for a hierarchical analysis that represented the second stage as in Figure 5.

Figure 3 A partial hierarchical analysis of a passage of text.

PTERIDOPHYTES or fern-like plants	possess	stem, leaves, roots	—	and fibro-vascular bundles	and are reproduced by **spores.**
Flowering plants	have	root, stem, leaves	flowers	and fibro-vascular bundles	and are reproduced by **seed.**
replacement of topic	repetition by paraphrase	repetition by same lexical items	replacement by addition	repetition by same lexical items(s)	replacement of means of reproduction

Figure 4 Patterns of repetition and replacement in two sentences from the botany passage.

Figure 5 An alternative (partial) hierarchical analysis of the botany passage.

The hierarchical model of clause relations also assumes that all texts conform to a particular monologue model. White's work on news stories, referred to above, would seem fundamentally incompatible with the hierarchical assumption of RST; my account of colony texts such as dictionaries and encyclopedias (Hoey, 1986, 2001) also challenged the assumption, though it is possible to represent such texts as a shallow hierarchy.

All of this work has been influential and RST in particular still has many adherents, but the study of clause relations, and their use in analysis (as opposed to the use of culturally popular patterns, which are related to clause relations in a variety of ways [*see* **Problem-Solution Patterns**]), is perhaps no longer central to text linguistics. Except in a crude and limited fashion, they are not part of the armory of tools used in systemic-functional linguistics despite RST's close relationship to that model, which has after all a textual dimension. Nor are they used in critical discourse analysis, perhaps the most productive branch of written discourse analysis at the present time; Fairclough (1989) provided a helpful list of analytical tools that might be brought to bear upon a text, and clause relational analysis is not among them. Clause relations are not much used in contemporary stylistics, although Winter, Hoey (e.g., Hoey and Winter, 1982), Coulthard (1990), and other linguists have made effective use of the concept in the past. It is not that the concept has been rejected but that it has slipped out of use.

The reasons for this relative current neglect are probably fourfold. In the first place, clause relational analysis is time consuming. Secondly, it is often hard to allocate a particular pair of clauses (or groups of clauses) to a particular category of relationship with confidence. Thirdly, it is often sufficient to know that an analysis can be done without needing to do it; a detailed analysis of a text may be true but unrevealing. Finally, and most importantly, clause relational analysis is, as currently normally conceived, text centered rather than writer/reader centered. As we have seen, Winter's original definition placed clause relations in the interpretation of text by a reader, not in the text itself, though a later definition by Hoey and Winter (1986: 188) tried, perhaps unsuccessfully (and certainly clumsily), to define clause relations both in terms of the reader and in terms of the textual product:

> A clause relation is the cognitive process, and the products of that process, whereby the reader interprets the meaning of a clause, sentence, or group of sentences in the context of one or more preceding clauses, sentences, or groups of sentences in the same discourse. It is also the cognitive process, and the product of that process, whereby the choices the writer makes from grammar, lexis, and intonation in the creation of a clause, sentence or group of sentences are made in the context of the other clauses, sentences, or groups of sentences in the discourse.

Widdowson (2004) emphasized that text does not have meaning on its own but that readers find meaning in texts on the basis of context and what they bring to the text. In such terms, any attempt to find **the** semantic structure of a text is inherently misguided. This is not to say that a text never contains clause relations independently of the reader's interpretation – the writer may have chosen to signal explicitly the relation that he or she perceived between two pieces of text – but it is to say that there is no single analysis possible of any text unless, improbably, every possible semantic relation has been explicitly signaled within it. Readers may differ both in the relations they find in a text and in the inventory of relations they have available to them for processing the text. Consider

again the first two sentences of the passage about Shakespeare's final year: "At the beginning of 1616 Shakespeare's health was failing. He directed Francis Collins, a solicitor of Warwick, to draft his will, but, though it was prepared for signature on January 25, it was for the time laid aside." They were represented as standing in a cause–consequence relation. But that is one reader's interpretation and is not explicitly signaled in the text. It would be open to another reader to read these as in the relation of simultaneity (a special sequence relation in which time sequence is denied), in which Shakespeare's decision to draft a will may have been unconnected with his failing health. I prefer my reading but the other reading has to be accounted for. The future of clause relational analysis must therefore lie in a closer integration with reading theory. Attempts to determine a single semantic structure may be misguided but attempts to find **possible** semantic structures are not. It would be unfortunate if the insights clause relational analysis offers were lost for lack of any attempt to bring it up to date.

Clause Structure in Spoken Discourse

J Miller, University of Auckland, Auckland, New Zealand

© 2006 Elsevier Ltd. All rights reserved.

Clauses in unplanned speech are simpler than clauses in planned writing, which can be edited. The differences lie in the simplicity of noun phrases (NPs) and in where less-than-simple NPs are positioned in clauses; in the lack of *to*-clauses, *ing*-clauses, and complement clauses in subject position and their abundance at the end of clauses; in the absence of sentences; and in constructions that are typical of unplanned speech or planned writing (although a good number of constructions are typical of both). The constructions typical of unplanned speech are regarded as reflecting its general characteristics, especially the lack of editing time, the limitations of short-term memory, and the fact that information is signaled not just by the verbal component of language but also by nonverbal components such as gesture, pitch and amplitude, and voice quality.

Not all analysts agree that unplanned speech has simpler clause structure (e.g., Halliday, 1989), but the disagreements can be explained in terms of formality (setting, topic, and participants). Greater formality generally leads to more complex language. Speakers also differ from one another. Speakers with long exposure to written texts produce complex language in unplanned speech. And the more experience speakers have of unplanned speaking in formal situations, the more likely they are to produce complex language.

NPs as a Measure of Complexity

Complexity is measured by two properties: the number of words in a phrase and of phrases in a clause, and the depth of embedding. NPs provide a good illustration. Miller and Weinert (1998: 146) found that in a sample of monologue, 50% of the NPs consisted of a pronoun and another 7% consisted of a single nonpronominal word. When NPs consisting only of a numeral (*give me two please*) or a quantifier (*I'd like more*) were counted, the percentage of one-word NPs rose to 64. Few NPs contained other constituents: 5.6% of the NPs contained an adjective, 6% contained a prepositional phrase (*the car outside the house*), and 3.2% contained a relative clause. There were no complex NPs, that is, NPs containing a combination of these constituents, as in *a new proposal from the agency, which is likely to be rejected*. In contrast, an analysis of the NPs in the letters to a newspaper (see Miller and Weinert 1998: 154) showed that 19.7% contained adjectives and 18.8% contained prepositional phrases (*every telephone exchange in the country*). Only 3% contained relative clauses, but 3% were complex, as in *a rigorous and valid examination on applied economics that consists of three papers*.

Counting alone is not sufficient; **where** types of NPs occur in clauses is also important. The main tendency is clear: in subject position speakers use simple NPs. In Thompson's data (1988), the subject NPs of transitive clauses did not have adjectives, although some subject NPs of intransitive clauses did. (Transitive clauses have object NPs and are more complex; intransitive clauses do not have object NPs.) In Miller and Weinert's spoken data (1998), no adjectives occurred in subject NPs; Crystal (1979: 164) found that in the conversations in the London-Lund Corpus, 77% of the clauses had as subject a pronoun or an 'empty' word such as *it* or *there*. The pattern is confirmed in Biber *et al.* (1999: 235–237).

Clause Structure in Spoken Discourse

J Miller, University of Auckland, Auckland, New Zealand

Clauses in unplanned speech are simpler than clauses in planned writing, which can be edited. The differences lie in the simplicity of noun phrases (NPs) and in where less-than-simple NPs are positioned in clauses; in the lack of *to*-clauses, *ing*-clauses, and complement clauses in subject position and their abundance at the end of clauses; in the absence of sentences; and in constructions that are typical of unplanned speech or planned writing (although a good number of constructions are typical of both). The constructions typical of unplanned speech are regarded as reflecting its general characteristics, especially the lack of editing time, the limitations of short-term memory, and the fact that information is signaled not just by the verbal component of language but also by nonverbal components such as gesture, pitch and amplitude, and voice quality.

Not all analysts agree that unplanned speech has simpler clause structure (e.g., Halliday, 1989), but the disagreements can be explained in terms of formality (setting, topic, and participants). Greater formality generally leads to more complex language. Speakers also differ from one another. Speakers with long exposure to written texts produce complex language in unplanned speech. And the more experience speakers have of unplanned speaking in formal situations, the more likely they are to produce complex language.

NPs as a Measure of Complexity

Complexity is measured by two properties: the number of words in a phrase and of phrases in a clause, and the depth of embedding. NPs provide a good illustration. Miller and Weinert (1998: 146) found that in a sample of monologue, 50% of the NPs consisted of a pronoun and another 7% consisted of a single nonpronominal word. When NPs consisting only of a numeral (*give me two please*) or a quantifier (*I'd like more*) were counted, the percentage of one-word NPs rose to 64. Few NPs contained other constituents: 5.6% of the NPs contained an adjective, 6% contained a prepositional phrase (*the car outside the house*), and 3.2% contained a relative clause. There were no complex NPs, that is, NPs containing a combination of these constituents, as in *a new proposal from the agency, which is likely to be rejected*. In contrast, an analysis of the NPs in the letters to a newspaper (see Miller and Weinert 1998: 154) showed that 19.7% contained adjectives and 18.8% contained prepositional phrases (*every telephone exchange in the country*). Only 3% contained relative clauses, but 3% were complex, as in *a rigorous and valid examination on applied economics that consists of three papers*.

Counting alone is not sufficient; **where** types of NPs occur in clauses is also important. The main tendency is clear: in subject position speakers use simple NPs. In Thompson's data (1988), the subject NPs of transitive clauses did not have adjectives, although some subject NPs of intransitive clauses did. (Transitive clauses have object NPs and are more complex; intransitive clauses do not have object NPs.) In Miller and Weinert's spoken data (1998), no adjectives occurred in subject NPs; Crystal (1979: 164) found that in the conversations in the London-Lund Corpus, 77% of the clauses had as subject a pronoun or an 'empty' word such as *it* or *there*. The pattern is confirmed in Biber *et al.* (1999: 235–237).

In unplanned speech subject NPs do not normally contain infinitives (e.g., *to see Naples and die would be idiotic*) or gerunds, whether simple gerunds such as *seeing Vesuvius erupting was the highlight of the trip* or complex gerunds such as *their missing the eruption of Vesuvius was unfortunate*. Biber *et al*. (1999: 754) found that *to*-clauses and *ing*-clauses (infinitives and gerunds) are relatively rare in conversation.

Complement clauses occur in unplanned speech, but not in subject NPs; examples such as *that she was leaving the company came as a surprise to everyone* are rare. Instead, in spoken English we find the construction called extraposition, which allows speakers to place infinitives, gerunds, and complement clauses at the end of clauses. It is called extraposition, the name reflecting the idea that the infinitives, gerunds, and complement clauses are really the subject but are out of position, as in *it would be idiotic to see Naples and die*, *the highlight of the trip was seeing Vesuvius erupt*, *it came as a surprise to everyone that she was leaving the company.* The construction allows speakers to produce the main predication, as in *it would be idiotic* and *it came as a surprise*, and to add the phrase specifying what *it* refers to. *It* is often analyzed as a dummy or empty subject pronoun; for unplanned speech it is tempting to analyze *it* as having a referent, one which has to be specified by the infinitive, and so on.

In many languages speakers avoid complex subject NPs by means of a construction consisting of an NP followed by a clause, as in *the guy that tried to lift it he nearly dropped it on his foot*. The speaker produces a complex NP which is not part of a clause – *the guy that tried to lift it* – and then produces the clause conveying information about the referent of the NP – *he nearly dropped it*. The initial NP need not be very complex; compare *the driver you get a laugh with him*, from the Edinburgh Corpus of Spoken Scottish English.

A very common construction in unplanned speech is *it's unfair what they're doing to the union* and *it is unreasonable what she suggests*. This construction allows the speaker to produce a clause containing the information that something is unfair or unreasonable and then to produce an NP specifying the something. As in the examples above, the complex NP is not integrated into a clause.

Number of Modifiers in Clauses

In unplanned speech there are severe limitations on the number of phrases modifying a verb in a single clause. Highly literate speakers can produce clauses such as *the duckling was killed by the farmer for his wife at dawn near the duck pond with a .357 Magnum*. In fact, clauses in unplanned spoken English typically contain just one or two NPs, subject and direct object, with at most three NPs: *he killed the duckling* and *he killed the duckling with his .357 Magnum*. An account of the event in unplanned spoken English will be along the lines of *the farmer went to the duck pond at dawn; he took his .357 Magnum and shot a duckling for his wife*.

The number of modifiers in clauses is affected by the distinction between given and new information. The constituents conveying given information (that is, information handled as being available to the listener) are regularly ellipted. Consider the following sequence from the Edinburgh Corpus of Spoken Scottish English. One participant asks *what's he going to do anyway that boy?* The reply is *play golf*; both *he* and '*s going to* have been ellipted.

What is merely typical in unplanned spoken English is obligatory in some languages that are spoken only. Munro and Gordon (1982: 111) suggested that in the Native American language Chickasaw, clauses can have only two modifiers per verb, and Lichtenberk made a similar comment with respect to the Austronesian language Toqabaqita (To'abaita) (Solomon Islands).

The number of modifiers is relevant to constructions expressing different perspectives on transitivity. Most clauses in unplanned speech and in formal writing are active, although the proportion of passive clauses increases in dense informative texts such as academic monographs and textbooks. Such texts do contain long passives such as *this scientist was criticized by theologians*; unplanned speech contains very few long passives but does offer short passives, such as *this scientist was criticized*.

Clause Structures (Un)Typical of Unplanned Speech

Certain clause constructions are quite untypical of spontaneous speech. These include gapping (*Jim washed and Margaret dried the dishes*), accusative and infinitive (*we consider her to be the best candidate*), possessive gerunds (*his having resigned before he even took up the post astonished everyone*), free participles (*browsing in the bookshop, I came across a book on Peter the Great)*, and participial phrases/reduced relative clauses (*the book rejected by the publisher*, *the plane sitting on the runway at Heathrow*).

In general there are fewer finite subordinate clauses in unplanned speech than in planned writing. Miller and Weinert (1998: 90–93) found that 25% of all the finite clauses in their conversational data were subordinate. Almost the same percentage occurred in fiction (26%), but a broadsheet newspaper had 41%, and a semiacademic journal 45%.

Finite adverbial clauses present a complex pattern. Thompson (1988) found the highest proportion of finite adverbial clauses in informal speech but looked only at monologues. Greenbaum and Nelson (1995: 186) found a low percentage of finite adverbial clauses in spoken English, a higher percentage in informal written texts, and the highest in formal written texts, but analyzed monologues, broadcast discussions, and conversation.

Adverbial clauses of condition, reason, and time are most frequent in speech, but what appear to be clauses of condition and reason are regularly used as main clauses. Commands are issued via 'conditional' clauses: *if you just put the parcel on the table*. Reason clauses behave like main clauses, even allowing tag questions, which are excluded from subordinate clauses: *cos it's too dear, isn't it*. In Miller and Weinert's data, concessions are expressed by means of main clauses ending in *though*: *you won't find many dogs here though*. Another construction currently in regular use in unplanned speech looks like an adverbial clause of concession, e.g., *although you won't find many dogs here*. Such clauses may be separated from surrounding clauses by a very long pause and do not combine with a main clause to form a 'sentence' or clause combination. The essential property of the construction is that *although* is uttered with a separate intonation and separated by a long pause from the main part of the clause. These occurrences of *although* look more like discourse particles than subordinating conjunctions.

Clefting in Spoken Discourse

Á Di Tullio, Universidad del Comahve, Neuquén, Argentina

© 2006 Elsevier Ltd. All rights reserved.

Syntactic Structure of Cleft Constructions

Among sentences that overtly exhibit the informational functions of their constituents, cleft constructions are special in that they achieve this effect by means of syntactic devices: the copula and a subordinator. As the informational functions of a constituent are concerned with its contribution to the insertion of the sentence in a given discourse, the information supplied by the context may be considered from two different angles: ground/focus and presupposition/assertion. The information that the speaker regards as active in the mental world of the listener is distinguished from the one introduced as new, on the one hand, and what is presented as granted or assumed from what is presented as prominent, on the other. In cleft constructions, the copula *be* and the subordinator are employed to focus a constituent, while placing the others in the background. Although the focused constituent is syntactically highlighted, it does not always provide new information.

'Cleft' is a polysemous word: as a cover term it will be used to refer to all constructions that involve clefting; they will be called 'cleft constructions.' It is also used to refer to a specific type of construction, 'it-cleft sentence.' The following are samples of cleft constructions:

(1a) It was the paper that Jeremy left on the desk yesterday.
(1b) What Jeremy left on the desk yesterday was the paper.
(1c) The paper was what Jeremy left on the desk yesterday.

Finite adverbial clauses present a complex pattern. Thompson (1988) found the highest proportion of finite adverbial clauses in informal speech but looked only at monologues. Greenbaum and Nelson (1995: 186) found a low percentage of finite adverbial clauses in spoken English, a higher percentage in informal written texts, and the highest in formal written texts, but analyzed monologues, broadcast discussions, and conversation.

Adverbial clauses of condition, reason, and time are most frequent in speech, but what appear to be clauses of condition and reason are regularly used as main clauses. Commands are issued via 'conditional' clauses: *if you just put the parcel on the table*. Reason clauses behave like main clauses, even allowing tag questions, which are excluded from subordinate clauses: *cos it's too dear, isn't it*. In Miller and Weinert's data, concessions are expressed by means of main clauses ending in *though*: *you won't find many dogs here though*. Another construction currently in regular use in unplanned speech looks like an adverbial clause of concession, e.g., *although you won't find many dogs here*. Such clauses may be separated from surrounding clauses by a very long pause and do not combine with a main clause to form a 'sentence' or clause combination. The essential property of the construction is that *although* is uttered with a separate intonation and separated by a long pause from the main part of the clause. These occurrences of *although* look more like discourse particles than subordinating conjunctions.

Clefting in Spoken Discourse

Á Di Tullio, Universidad del Comahve, Neuquén, Argentina

© 2006 Elsevier Ltd. All rights reserved.

Syntactic Structure of Cleft Constructions

Among sentences that overtly exhibit the informational functions of their constituents, cleft constructions are special in that they achieve this effect by means of syntactic devices: the copula and a subordinator. As the informational functions of a constituent are concerned with its contribution to the insertion of the sentence in a given discourse, the information supplied by the context may be considered from two different angles: ground/focus and presupposition/assertion. The information that the speaker regards as active in the mental world of the listener is distinguished from the one introduced as new, on the one hand, and what is presented as granted or assumed from what is presented as prominent, on the other. In cleft constructions, the copula *be* and the subordinator are employed to focus a constituent, while placing the others in the background. Although the focused constituent is syntactically highlighted, it does not always provide new information.

'Cleft' is a polysemous word: as a cover term it will be used to refer to all constructions that involve clefting; they will be called 'cleft constructions.' It is also used to refer to a specific type of construction, 'it-cleft sentence.' The following are samples of cleft constructions:

(1a) It was the paper that Jeremy left on the desk yesterday.
(1b) What Jeremy left on the desk yesterday was the paper.
(1c) The paper was what Jeremy left on the desk yesterday.

The sentences in (1) exemplify the two main types of cleft constructions: (1a) is a cleft sentence (also named 'it-cleft' or 'true cleft'), and (1b) and (1c) are pseudocleft sentences (also called 'wh-cleft'), in their basic and reversed version, respectively. Cleft and pseudocleft sentences may be connected to a simpler, undivided sentence (2):

(2) Jeremy left the paper on the desk yesterday.

Syntactically, cleft constructions are biclausal copulative sentences. Both clauses are linked by a shared constituent, tacit in the subordinate clause, as direct object of *left*, but explicit as complement of the copula in the matrix clause: the noun phrase (NP) *the paper.*

(3) It was **the paper** that Jeremy left__on the desk yesterday.

From a semantic perspective, cleft constructions are specificational copulative sentences. A description that predicates on a certain kind of object – *Jeremy left* ***something*** *on the desk* – is specified by the focused constituent, whose referent appears as the only object that renders it true, namely *the paper.*

From a pragmatic point of view, cleft constructions are emphatic copulative constructions, for they contain a focused constituent that corrects a piece of information of the precedent discourse (an actual sentence or presupposed information). Such focus attains contrastive meaning because it rejects all other alternatives of the same category. The structure of the subordinate clause reproduces that of the original sentence:

(4a) Jeremy left the book on the desk yesterday.
(4b) No, it was **the paper** that Jeremy left on the desk yesterday.

The complexity of these constructions is evident in each of the levels, as well as in the intricate relationships holding between them. As a consequence, they have received continued attention from grammarians, who are interested in accounting for their syntactic anomalies, and from pragmaticians, who focus more on their informative functions. On the other hand, clefts are sensitive to differences in registers: in colloquial English, for example, a pleonastic construction, such as *What Jeremy left on the desk is Jeremy left a paper*, is common at all sociolects; in spoken Spanish, the most frequent cleft is *(Lo que pasa) es que* ... ('What happens is that ... 'or 'it is that'), an explicative resource for the preceding sentence.

The general syntactic characteristics of cleft constructions will be analyzed in the next section, starting from their components: the copula, the subordinate clause, and the focused constituent. Then the types of cleft constructions, namely cleft sentences, pseudocleft sentences, and some other minor types, will be differentiated in English and Spanish. Finally, the discursive value of cleft constructions in spoken discourse will be examined.

Cleft Constituents: Configurational Definition and Process Definition

Cleft constructions can be described in two alternative ways. In configurational terms, each class denotes a sentence type consisting of a certain sequence of constituents in a particular order, which takes the following form in English:

(a) It-cleft: It + copula + focused constituent + 'relative' clause.
(b) Basic pseudocleft: Free relative clause + copula + focused constituent.
(c) Inverted pseudocleft: Focused constituent + copula + free relative clause.

The it-cleft sentence is characterized by its first segment: a dummy subject, *it*, followed by the copula, and a noncanonical relative. In pseudocleft sentences the copula occupies an intermediate position between a free relative clause and the focused constituent.

However, 'cleft' is associated with 'clefting,' a process term. In this sense, it may involve the operation of splitting an undivided simpler sentence into two clauses. The three cleft constructions in (1) are different expansions of the basic sentence (2). In effect, sentence (2) describes the same state of things as the three sentences in (1), expressed via an identical argument structure, with the same illocutionary force and truth value. This equivalence holds, regardless of any commitment to an actual psychological operation or to a derivational analysis of these constructions. In fact, the process may be understood as an expository device to depict a relationship holding between sentences.

Each of the complements or adjuncts of the undivided sentence (2) can be cleft. The focused phrase may be an NP (direct object, or DO, in (1), the subject in (5a); a prepositional phrase, PP, or an adverbial phrase, AdvP (5b); or a nontensed (5c) or tensed clause (5d):

(5a) It was *Jeremy* who left the paper on the desk yesterday.
(5b) It was *on the desk/yesterday* that Jeremy left the paper.
(5c) What Jeremy did was *to leave the paper on the desk yesterday.*
(5d) What happened was that Jeremy left the paper on the desk yesterday.

In contrast, neither atonic elements (determiners, clitic pronouns, auxiliaries) nor peripheral constituents

(supplement modifiers, disjuncts, vocatives) are cleft. When the focused constituent is an NP, as in (1), all three types of cleft constructions are possible. Clauses, in contrast, are nearly exclusively foregrounded by means of basic pseudocleft sentences. In these, free relatives may introduce lexical units that are not present in the simpler sentence: the verb *do* in (5c) signals that the focused nonfinite clause is headed by an action verb; the verb *happen* in (5d) does not distinguish between types of predicates.

Contrary to the case of pseudocleft sentences, it-clefts always have undivided correlates. It is possible to cleave only one constituent (6a), usually lighter in 'it-clefts' or 'reversed-pseudoclefts'; heavier in 'basic pseudoclefts,' with the exception of the combination of a temporal and a locative expression, which functions as a single constituent, indicating a spatiotemporal setting:

(6a) *It was **the regional paper on the desk** that Jeremy left.
(6b) It was **in Malta in 1945** that the treaty was signed.

Value of the Copula: Specificational Copular Sentences

The copula *be* is a relational word that conjoins the subject and a predicative expression. It provides inflectional information, both manifesting subject/predicate agreement features and indicating the temporal setting of the state or relationship. Three types of copular sentences are usually identified, as follows.

First, in predicational copular sentences, the predicative complement assigns a property to the referent of the subject or ascribes it to a class: *the grammar professor is funny/vegetarian/my mother's neighbor.* Secondly, identificational copulative sentences establish an identity between two potential referring expressions. Thus, in *the grammar professor is Julia's husband/Ignacio/that one*, the referent of the subject is identified as the same person as the referent of the copular complement. Although the resulting sentence is also grammatical when the order is reversed – *Julia's husband/Ignacio/that one is the grammar professor* – the change in order entails different interpretations, which are pragmatically justified. If the listener is able to match both referring expressions, the complement of the copula becomes referential.

In the third type, specificational sentences, the identification proceeds in the opposite direction (7a). It is the one to which cleft constructions belong. The variable contained in an open proposition is specified by the referential expression in focus position (7b). As a consequence of this relation variable/value, the specification provides two pieces of information that the noncopular sentence (2) lacks: the referent of the focused phrase (thing, person, property, proposition), whose existence is presupposed, is the only one that satisfies the description (exhaustivity, [7c]), thus rejecting all other possible referents (contrastiveness, [7d]):

(7a) Jeremy left something on the desk: the paper.
(7b) The x such that Jeremy left x on the desk = the paper.
(7c) The paper is the **only** thing that Jeremy left on the desk.
(7d) The only thing that Jeremy left on the desk is the paper, **not the book.**

Although all cleft constructions are specificational, pseudoclefts form part of a broader paradigm. The initial description may be a (semi)free relative clause or else a definite NP, a general noun perhaps modified by a superlative expression. The demarcation line between free relative clauses (or even semifree relatives with demonstrative pronouns) and NPs with a restrictive modifier is not always neatly drawn cross-linguistically. In pseudoclefts the relative pronoun provides only grammatical information on the missing phrase, but the nominal elements in (8b) add lexical information: the copular complement may be an instantiation or hyponym of the subject head:

(8a) The one who left the paper on the desk was Jeremy.
(8b) The person who left the paper on the desk was Jeremy.
(8c) The person who read the most papers is Jeremy.

On the contrary, as the three types of copulative sentences can have free relative clauses as subjects, ambiguity may arise as regards their predicative or specificational character, as seen in (9):

(9a) What he told you is fiction.
(9b) What John is is necessary.

The complement of the copula in (9a) may be interpreted as evaluative ('an invention') or else as a work of literature; only in the latter case is the sentence specificational. Sentence (9b) is ambiguous as well: in its specificational reading, *necessary* picks up the defining feature of *John*, and not that of his profession, as in the predicational interpretation. This type of ambiguity, frequent in pseudoclefts, is rare in cleft sentences.

In predicational and identificational copular sentences, the copula has independent temporal information: tense situates the predicate in a point in time. In cleft constructions, copular tense is not an informative grammatical unit but rather a dependent category: it may be a default tense, the present, or a tense copied from the inflection of the subordinate clause.

The directionality of this influence also shows that the copula is not the main verb of the sentence but a defective verb, almost an auxiliary. However, modality marks as auxiliaries, tenses, or adverbs can modify the copula independently of the principal verb: *it will/would be the paper that Jeremy left on the desk*.

In the syntactic structure of pseudocleft sentences, the copulative verb is placed in the habitual position between the subject and its complement. The position of the copula is less canonical in it-clefts. In fact, the copular segment – *it is* – appears to be a focalizing device rather than the matrix clause. The initial copula does not permit changes in order. This rigidity is accounted for in terms of the restrictions on copula position: because it must be adjacent to the focused constituent, it cannot be final; the 'relative clause' can appear only in final position.

Subordinate Clauses: Relative Pronouns or Conjunctions

The free relative clauses in pseudoclefts are semantically versatile constructions, able to represent the different denotations listed in (10):

(10a) NP non personal: What I need is money.
(10b) PP place: Where he found it was on the desk.
(10c) AdvP time: When I met you was spring.
(10d) AdvP manner: How he fought was courageously.
(10e) NP or AdjP quality: What he is is a bastard/is important.
(10f) Verb phrase (VP) action: What he is doing is hitting the door.
(10g) Clause: What he said is that he is tired of the noise.

Relative pronouns anticipate the semantic type of the focused constituent. But in it-clefts, the complementizer *that* lacks semantic information; in fact, it may even be empty: *it was this paper Jeremy read yesterday*; when the relativized unit is a human noun, the relative pronouns *who, whose*, or *whom* carry grammatical information about the case.

It-clefts are not susceptible to a wholly satisfactory binary analysis: neither *It is the paper/that Jeremy left on the table* nor *It is/the paper that Jeremy left on the table* is an adequate analysis. In the first segmentation, it is not clear what function the subordinate clause performs. The problem with the second one is that the focused constituent and the 'relative' clause do not form a constituent, as the contrasts in (11) show:

(11a) It was the paper that Jeremy left on the desk.
(11b) I didn't find the paper that Jeremy left on the desk.

(12a) It was Jeremy who left he paper on the desk.
(12b) Jeremy, who left the paper on the desk, has been looking for it.

Unlike (11b), the 'relative clause' in (11a) does not restrict the antecedent *paper*, but rather it is an open clause to be specified. In (12b), the relative clause is not restrictive, as the comma indicates, while in (12a) the relative clause after *Jeremy* is not marked by means of a separate tonal group as in the non-restrictive relative clause in (12b) is. Nor is the subordinate clause a complement clause: there is no selector word, and it is not a complete sentence for it contains a missing phrase specified by the focused constituent, as the contrast with an extraposed omplement clause portrays (13a and 13b):

(13a) It is unlikely that my son will return this week.
(13b) That my son will return this week is unlikely.
(13c) It is the paper that John left__on the desk yesterday.
(13d) *That John left on the desk yesterday is the paper.

The subordinate clause in it-clefts is not canonically relative, nor is it a complement clause, but rather a focusing modifier, and so a special 'relative clause' (thus the use of quotation marks).

The Focused Constituent

It-/wh-clefts present differences regarding the categorial options of the focused constituent. As it-cleft only permits referential phrases, NPs or PPs, it rejects negative or universally or existentially quantified phrases, as well as phrases preceded by a focalizer such as *even* or *also*:

(14a) *It was nobody/somebody/everybody that came.
(14b) *It is even/also money I need.

The rejected phrases contradict the semantic conditions of cleft constructions: existence, exhaustivity, and contrastivity. Yet, adverbs like *precisely, exactly,* and *justly*, are perfectly compatible with such contents.

Wh-clefts are less restrictive: the focused constituent may be not only a referential expression but also a predicative one: an AdjP or usually a clause. It must be semantically congruent with the relative pronoun. On the other hand, the focused constituent of reversed pseudoclefts differs as much in categorial restrictions as in their 'weight': the cleft constituent, topicalized as subject, is generally an NP, specifically a pronoun:

(15a) That is what I said.
(15b) Here is where I live.

The category and weight of the focalized constituent, then, in clefts and reversed pseudoclefts, are similar: a light phrase as an NP, generally pronominal (*that*), or else a deictic or anaphoric adverb (*there, then, so*). Basic pseudoclefts usually focalize heavy constituents, usually clauses. A paradigm such as (1) is possible, then, only with nominal constituents.

In conclusion, the paradigm in (1) can lead to the misguided idea of a perfect symmetry among the three members. Nevertheless, the differences regarding the focused constituent displayed by the two versions of pseudoclefts are not dependent only on word order. The most outstanding distinctions are to be found between it-clefts and the rest of cleft constructions: the nonreversible order of their constituents and their peculiar 'relative clause.' These sentences prove unsuitable for dichotomous categories as regards constituency, syntactic functions, nature of the subordinate clause, and value of the copula. Most of these anomalies arise from their high degree of grammaticalization.

Types of Cleft Sentences

The structural realization of informative functions reflects crosslinguistic diversity. These differences are connected to the structural features of languages. In languages with strict word order, intonation is exploited for informational purposes: in Germanic languages, in general, nuclear stress falls on the focalized constituent, regardless of the position it occupies. Cleft constructions are more sophisticated alternative strategies, for they trigger syntactic mechanisms. Strict word orders render them useful compensatory devices. In languages with more flexible word order, the movement of the focused constituent to initial position – obligatory in Hungarian, optional in others, such as Spanish, Italian, or Portuguese – does not need clefting; yet, cleft constructions reinforce the focal status of the displaced constituent. Some nonconfigurational languages – e.g., polysynthetic languages such as Quichua, Toba, and Mapuche (Mapudungan) – lack clefts.

In Spanish or Portuguese, word order on its own does not make it possible to differentiate clefts from pseudoclefts, since the latter present three possible orderings. In Italian it-clefts, the 'relative clause' (16a) alternates with the infinitive verb preceded by the preposition *a* (16b) when the focused constituent is an agentive subject; in Portuguese and American Spanish, only the first option is available. Both Italian and Portuguese admit focused NPs in it-clefts, while in American Spanish only PP or adverbials are possible:

(16a) è (stato) Gianni che lo ha detto
is (been) Gianni that has said it

(16b) è stato Gianni a dirlo
is been Gianni a to say it

(16c) foi o bolo che comeu Joao
was a cake that ate Joao

(16d) *Fue la torta que comió Juan
**Was the cake that ate Juan*

Genetically and typologically related languages deploy, then, different strategies (Smits, 1989). Furthermore, cleft constructions are not only interlinguistically but also interdialectically divergent, as is the case in Spanish.

Additionally, there are marginal varieties of canonical clefts and pseudoclefts, particularly in spoken discourse: reduced clefts, conditional clefts, and inferential or eventive clefts, which will be presented below. Other possibilities are also available, such as this-cleft, all-cleft, and there-cleft. In spoken French, *avoir*-cleft, or presentational cleft (Lambrecht, 1988), makes use of segmentation in order to introduce a new referent in a given discourse or as event-reporting statements:

(17a) j'ai ma voiture qui est en panne
I have my car that is breakdown
'my car broke down'

(17b) y'a le téléphone qui sonne
there-has the telephone that rings
'the phone's ringing'

All these varieties are specificational but, as some of the typical constituents are missing, they imply a broader definition of cleft constructions, which not all linguists are open to accepting.

Spanish Clefts and Pseudoclefts

Spanish pseudocleft sentences admit three possible orders; grammars call them 'relative periphrasis':

(18a)	fue	eso	lo que	dijo	Juan
	was	*that*	*what*	*say*-PAST 3PERS	*John*
	'that was what John said'				
(18b)	lo que	dijo	Juan	fue	eso
	what	*say*-PAST 3PERS	*John*	*was*	*that*
	'that was what John said'				
(18c)	eso	fue	lo que	dijo	Juan
	that	*was*	*what*	*say*-PAST 3PERS	*John*
	'that was what John said'				

When the focused constituent is a personal pronoun, it determines the inflectional features of the copula but not those of the verb in the relative clause. In any of the orders, the relative pronoun imposes third person agreement:

(19a)	soy	yo	la	que	ha	sido	acusada
	be.PRE 1SING	*I*	*the*-FEM	*that*	*has*	*been*	*accuse*-PAST FEM
	'I'm the one who's been accused'						

(19b) la que te miras en el espejo
the-FEM that look yourself at mirror
eres tú
are you
'the one who is looking at herself in the mirror is you'

If the focused constituent is a PP, the relative pronoun reproduces the preposition in all three orders:

(20a) de la que (quien) todos hablan es de la mujer del presidente
about the one who everybody talks is about the president's wife
'the one everybody talks about is the president's wife'

(20b) de la mujer del presidente es de la que (quien) todos hablan
about the president's wife is about the one who everybody talks
'the president's wife is the one everybody talks about'

(20c) es de la mujer del presidente de la que (quien) todos hablan
is about the president's wife about the one who everybody talks
'it is about the president's wife that everybody talks'

Both European Spanish and American Spanish possess pseudoclefts, yet only American Spanish has real clefts, which are unacceptable for normative grammars. These (it)clefts, characteristic of spoken discourse, are nonreversible constructions in which the relative clause is introduced by the complementizer *que* alone. In these sentences the focused constituent, a PP or AdvP, can be pre- or post-copular:

(21a) es de la mujer del presidente que todos hablan
is about the president's wife that everybody talks
'it is about the president's wife that everybody talks'

(21b) de la mujer del presidente es que todos hablan
about the president's wife is that everybody talks
'it is about the president's wife that everybody talks'

A third variety, limited both dialectically and sociolinguistically, is found in nonstandard registers of Caribbean Spanish, as well as in Portuguese, especially Brazilian: in it, the copula becomes a focalizing device, practically frozen in tense and agreement:

(22a) todos hablan **es** de la mujer del presidente
*everybody talks **is** about the president's wife*
'it is the president's wife everybody talks about'

(22b) Juan come es papa/papas
John eats is potato/potatoes
'what John eats is potato(es)'

Truncated Clefts

In spoken discourse, truncated cleft constructions, as (23), lack subordinate clauses, although the omitted clause is still recoverable from the context. The missing information is a cohesive resource and functions as a means of segmenting the flow of information in shorter units:

(23a) A. Who left the paper on the desk? B. It was Jeremy.

(23b) Yesterday two cars crashed head-on. It was on the bridge.

Spanish and other null subject languages have not only cleft but also pseudocleft reduced variants. In (24a) and (24b), the omitted part is the focused constituent, but as it is a pronominal, *this* or *that*, or an adverbial unit, *here or there*, it is inferable from the context or situation. In (24c) the omitted clause is recoverable from the situational context. The speaker wants to identify himself as the person who is speaking, on the telephone, for example. Although the verb is in the first person, the insertion of the personal pronoun in preverbal position would be inappropriate in such a context:

(24a) es lo que yo digo
is that I say
'that is what I say'

(24b) es donde nos encontramos siempre
is where we meet always
'that is where we always meet'

(24c) soy Juan
am Juan
'I am Juan'

Some constructions that have been analyzed as a peculiar type of cleft are those that are reduced to the two characteristic syntactic devices of clefts, *es que (it is that)* in strict adjacency in (25) and interrupted by the anticipated subject in (26). As reduced versions of basic pseudoclefts, the focused constituent is the entire clause; the lack of a variable guiding the interpretation is compensated for by a specific relationship with the context: as an explanation, in terms of causes, reasons, results, or conclusions (Delahunty, 2001; Declerck, 1992a), and as the identification of a perception. It is precisely by virtue of this relation that they are termed 'inferential' (25) and 'eventive' (26), respectively.

(25a) ¿por qué no te quedas a comer? – Es que estoy apurada
'why don't you stay for lunch? – it's because I'm in a hurry'

(25b) no es que me disguste, sino que no tengo hambre
'it is not that I don't like it, rather I'm not hungry'

(26a) ¿qué pasa? – Es Juan que acaba de llegar
'what's happening? – it's Juan who's just arrived'

(26b) ¿Qué ruido es ese? – Es el teléfono que está sonando
'what's that noise? – it's the phone ringing'

The sequence *es que*, which corresponds to *é che, c'est que, it is that,* has been analyzed in Spanish as a conversational marker resulting from a reanalysis produced by grammaticalization. In fact, a subject may be added, as *eso* 'that,' *la verdad* 'the truth,' *lo que pasa* 'what happens': these expressions indicate the pertinence of the explanation to a previous sentence. However, the cleft status of these sentences is proved by possible inflectional features of the copula, modification by means of modal auxiliaries, and the presence of negation, inducing subjunctive.

Conditional Clefts

The structure of conditionals also provides a segmented syntactic scheme: the copula in the if-clause foregrounds a particular constituent (27) or else the whole sentence (28), placed in the main clause:

(27a) si quiere a alguien, es a su hijo
if loves anybody, is to his/her son
'if there is anyone he/she loves, that is his/her son'

(27b) si se entusiasma con algo, es con la computadora
if is enthusiastic with anything, is with the computer
'if he/she gets enthusiastic about anything, it is the computer'

(28a) si dijo eso, es (por)que está resentida
if said that, is because is resented (FEM)
'if she said that, it is because she feels resentful'

(28b) si lo acepta, es para que la vuelvan a invitar
if accepts it, is for to be invited again
'if he/she accepts, it is because he/she wants to be invited again'

These are also specificational sentences, in which the focused constituent specifies the value of a variable, the indefinite pronoun situated in the if-clause, but they differ from clefts in that they are interpreted as high degree quantified expressions. On the other hand, when the variable that is specified is an adjunct, it does not have to be explicit, as can be seen in (28), where the clause is understood as an explanation, causal in (28a) and final in (28b).

In conclusion, the differences between cleft constructions in Spanish and English stem from idiosyncratic characteristics of these languages. In European Spanish, cleft strategies have shown a high degree of redundancy in pseudoclefts, contrasting with the economic device in Caribbean Spanish. The copula is grammaticalized in American Spanish clefts, merely reinforcing the displacement of focus.

The analysis of the three groups of cleft constructions has allowed us to see that the syntactic device copula-subordinator foregrounds two types of constituents: phrasal referential expressions on the one hand and clausal units on the other. It-clefts and reversed pseudoclefts foreground referential constituents. Both types constitute a natural class, as evidenced by the lightness of the constituents and the inverted variable-value order. Basic pseudoclefts are specialized in focusing clauses, heavy constituents that occupy the final position according to a fixed order: first variable, then value.

Reduced versions of each type follow this pattern. Conditional structure presents both kinds as well. Yet *es que* is specialized in focalizing clauses: the relationship with the context (linguistic or nonlinguistic) is necessary to infer the missing link so as to build up the explanation. The specification of the value of an entire clause is, then, performed directly when the variable is supplied in the free relative clause, or indirectly when it is necessary to infer it from context. The vagueness and indeterminacy of texts render this specification not always an easy task (Sornicola, 1989).

On the other hand, it-cleft sentences are more frequent in written discourse, not only in English but also in Spanish (Sedano, 1990). The more canonical character of pseudoclefts explains the wider paradigm, which includes colloquial constructions such as *What he looked up was he looked up a linguistic term,* semifree relatives (8a), and hyperonyms nouns modified by relatives (8b).

Cleft Constructions in Spoken Discourse

The focused constituent has been considered so far as a syntactic constituent of cleft constructions. In this section, in contrast, it will be analyzed from the perspective of the informational functions it performs. The focus of cleft sentences, intonationally and syntactically marked, is involved in two information partitions: focus/ground and assertion/presupposition. The first partition is realized through word order, from what is anchored in the preceding discourse or in the situational context to the new information. The second partition is expressed in clefts by

means of the biclausal structure. The subordinate clause contains the information regarded as presupposed, while in the matrix clause, which conveys the assertion, the focus is the lexical element.

These two information partitions may well coincide or intertwine. In the first case, the subordinate clause indicates old-discourse information, GROUND, while the focused constituent is in charge of the new-discourse information, FOCUS. That is what generally occurs in pseudoclefts, as (29) shows:

(29) "¿Me desvío otra vez? No creo, no soy yo el que se desvía, **la que se desvía es la historia**. . . . **Lo que me lleva también a desviarme es la intensidad, la tragicidad de los hechos que narro, desbocados todos excesivos.**"

'Am I diverting again? I don't think so, it's not me who diverts, it is history that diverts. . . . what leads me to divert is the intensity, the tragic nature of the events I narrate, bolted, all excessive' (Feinman, 2003: 163).

In the succession of cleft constructions that answers the initial question, the speaker picks up already uttered words, correcting some – a nominal as well as a verbal one – and reproducing the rest. The question subject is first negated and then taken up in a semifree relative clause: *la que se desvía*, whose variable is specified with the referent of the focused constituent as the value that exhaustively and exclusively satisfies it. In the next sentence, *Lo que me lleva también a desviarme*, it is the verb, modified by a modal, that is reintroduced with contrastive meaning.

In it-clefts, on the contrary, the focus may also introduce new information (30a) or, in most cases, establish a relationship with the context, as information already introduced in the listener's 'mental world' but syntactically highlighted (30b); in reversed pseudoclefts (30c), the focus is topicalized as well as the subject; thus it is nearly always thematic:

(30a) A. Tiene el doctorado hecho en Estados Unidos. B. ¿Pero es en Lingüística que era el doctorado? (Barrenechea, 1971: 2, 13)
A. He/she has finished the Ph.D. in the United States. B. But, is in linguistics that the Ph.D. was?

(30b) Buenos Aires era la ciudad centralizadora. Es esa la imagen que yo tenía de Buenos Aires hasta hace poco
'Buenos Aires was the centralizing city. It was the image that I had of Buenos Aires . . .' (Barrenechea, 1971: 1. III, 59)

(30c) eso fue lo que dijo
'that was what he said'

In fact, presupposition does not necessarily mean old discursive information; it can be either old or new information depending on the order of the constituents and on the type of cleft construction. The clause usually contains the new information both in clefts and in reversed pseudoclefts, their foci generally transmitting already known or inferable information, as frequently shown by their pronominal realization. The free relative clause in basic pseudoclefts, in contrast, tends to be the cohesive portion.

Thus, focus may be either strongly cohesive or strongly novel. When it is cohesive, as in clefts and reversed pseudoclefts, it may lose its contrastive value, becoming a mere emphatic resource: in fact, (31a) does not necessarily indicate that the event took place in that particular year, but rather it is normally interpreted without a contrastive sense. When the focalized constituent has discourse-old information, the relative clause may contain the contrastive value, shown in paralelism in (31b):

(31a) It was in 1932 when my family immigrated to Argentina

(31b) It was then when you gave me **the paper**, not **the keys**

Then, the focused constituent is available not only as a contrastive resource but also as a cohesive or an emphasizing device. The importance of two information partitions comes from the way in which cleft constructions establish their particular relationship with the context: when the speaker specifies the value of a variable, he/she foregrounds a piece of information, contrasting with another explicit or inferred textual piece or acting as if the contrast did exist actually. Indeed, the metalinguistic nature of cleft constructions can be explained through this conversational dynamic, which accounts for most of the syntactic and semantic anomalies detected.

Clitics

A D Caink, University of Westminster, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Term and Definitions

The term clitic is used in traditional grammar for a word or particle that cannot bear accent or stress and leans on an adjacent accented word (from Greek *kli:no* 'lean'). It includes both enclitic and proclitic elements. An enclitic morph joins to the end of an adjacent word, such as the reduced form of the English auxiliary verb *have* in (1), which is cliticized to the subject pronoun. It cannot appear in the question in (2) because it lacks a host to its left. A proclitic element attaches to the beginning of a word, such as the reduced form of the English auxiliary verb *do* in (3):

(1) they'**ve** decided against it.
(2) * '**ve** they decided against it?
(3) **d**'you need to decide today?

Some clitics may be proclitic in one context and enclitic in another, such as in Macedonian, where pronominal clitics are proclitic on the finite verb (4a) and enclitic on the gerund (4b) (see Franks and King, 2000).

(4a) **mi** **ja** dadoa smetka-ta
me.DAT it.ACC gave.3.PL bill-DEF
'They gave me the bill'

(4b) davajki **mi** **ja** smetka-ta, . . .
give.GER me.DAT it.ACC bill-DEF
'Giving me the bill, . . .'

Items that are clitic vary across languages but are always grammatical (or functional) words and thus members of closed classes in that they cannot be coined (Emonds, 1985: Chap. 4); they may include auxiliary verbs, pronouns (as in many Indo-European languages), question particles (Slavic *-li* in (9) or Finnish *-ko* in Nevis, 1988: 9), negative particles (Slavic verbal negation *ne* -in (9)), and conjunctions

Term and Definitions

The term clitic is used in traditional grammar for a word or particle that cannot bear accent or stress and leans on an adjacent accented word (from Greek *kli:no* 'lean'). It includes both enclitic and proclitic elements. An enclitic morph joins to the end of an adjacent word, such as the reduced form of the English auxiliary verb *have* in (1), which is cliticized to the subject pronoun. It cannot appear in the question in (2) because it lacks a host to its left. A proclitic element attaches to the beginning of a word, such as the reduced form of the English auxiliary verb *do* in (3):

(1) they'**ve** decided against it.
(2) * '**ve** they decided against it?
(3) **d**'you need to decide today?

Some clitics may be proclitic in one context and enclitic in another, such as in Macedonian, where pronominal clitics are proclitic on the finite verb (4a) and enclitic on the gerund (4b) (see Franks and King, 2000).

(4a) **mi** **ja** dadoa smetka-ta
me.DAT it.ACC gave.3.PL bill-DEF
'They gave me the bill'

(4b) davajki **mi** **ja** smetka-ta, . . .
give.GER me.DAT it.ACC bill-DEF
'Giving me the bill, . . .'

Items that are clitic vary across languages but are always grammatical (or functional) words and thus members of closed classes in that they cannot be coined (Emonds, 1985: Chap. 4); they may include auxiliary verbs, pronouns (as in many Indo-European languages), question particles (Slavic *-li* in (9) or Finnish *-ko* in Nevis, 1988: 9), negative particles (Slavic verbal negation *ne* -in (9)), and conjunctions

(Latin *-que* 'and'). There are no clitic forms for open-class items such as the lexical noun *wood*, despite the homophony with the modal auxiliary *would* (cf. *I'd really like that*).

In formal research, the term clitic is often used to refer only to pronominal clitics as in (4) that have proved to be of particular interest in terms of phonology, morphology, and syntax and the interfaces between these components of the grammar. A clitic cluster is formed when clitic elements in a language appear adjacent to one another, usually in a strict order and often in a fixed position in the clause, even in apparently free–word order languages. In some formal approaches, the clitic cluster may be a primitive of the system with its own rules of clitic order (e.g., Perlmutter, 1971). For many (particularly syntactic) approaches to clitic placement, clitic cluster is a descriptive term, an epiphenomenon of the prosodic properties of clitics and their placement.

In some languages, the position of the clitic cluster is restricted to the second position in the sentence, termed the Wackernagel position after the German 19th-century philologist (Wackernagel, 1892). The second position varies across languages between 'following the first phonological word' (e.g., Ancient Greek; Kaisse, 1985: 80) and 'following the first constituent' (e.g., Finnish; see Nevis, 1988: 19). Other languages allow for both second positions (e.g., Luiseño (Uto-Aztecan); see Kaisse, 1985: 85). To some extent, this is true of Serbo-Croatian, a language whose second position has attracted much debate in recent years (Bošković, 2001: 12):

(5a) taj čovek **je** volio Milenu.
that man aux.3.SG loved Milena
'that man loved Milena'

(5b) taj **je** čovek volio Milenu.
that aux.3.SG man loved Milena
'that man loved Milena'

The clitic auxiliary *je* follows the first constituent in (5a) and the first phonological word in (5b). Recent research on Serbo-Croatian demonstrates that the clitic cluster is restricted from intervening within some initial constituents, that there is substantial native speaker variation, and that the size of the clitic cluster is a factor (see Bošković, 2001: Chap. 2). For cross-linguistic debate on second-position phenomena see articles in Halpern and Zwicky (1996) and for Slavic generally see Franks and King (2000).

A distinction is made between syntactic cliticization and prosodic cliticization. Hence, in the sequence A – *b* – C where *b* is a clitic, it may be the case that *b* is syntactically proclitic on C, but prosodically enclitic on A, for example, the Australian language Nganhcara (Klavans, 1985: 104–105) and Bulgarian (see (9)) (Franks and King, 2000: 63).

Affixes, Words, and Clitics

The fundamental characteristic of clitics is that in some ways they behave like affixes (e.g., the past tense affix *–d* on the verb in (1)) and in some ways they behave like independent words (Sapir, 1930: 70–71), with much cross-linguistic variation. For example, affixes are highly restricted as to their host, whereas words tend to subcategorize for phrases, if at all. Pronominal clitics in many Indo-European languages are similarly restricted to appearing on a verb (as in Bulgarian (9) and French (10)), but this contrasts with Serbo-Croatian pronominal clitics, which do not distinguish between the category of host (see (5) and (7)). Similarly, the English possessive *'s* is dependent on whatever the last word of the preceding noun phrase happens to be (*the man I saw's hat; that man I gave a dollar to's hat*). As a result, it can be termed a phrasal affix.

Also, affixes are subject to word-internal phonological processes to which adjacent words are not subject. In Macedonian, the antepenultimate stress rule exemplified in *žénata* 'the wife' is followed even when the possessive clitic *ti* 'your' is added to form *ženáta-ti* 'your wife'; the clitic appears to be part of the phonological word in the same way as a suffix, and the stress shifts accordingly (see Spencer, 1991: 360). Yet, in Latin, the enclitic *-que* 'and' is not subject to the rule that assigns main stress in a word. This rule does not ordinarily assign primary stress to the penultimate syllable if it is strong, but primary stress still appears on the strong penultimate syllable in the word + clitic *rosáque* 'and the rose (NOM)' (Nespor and Vogel, 1986: 115–116; for other word-internal rules in relation to clitics, see Kayne, 1975: 85, and Nespor and Vogel, 1986: Chap. 5).

Affixes generally appear in a strict order, and, if this order varies at all, then there is a concomitant change in meaning. Most languages with a clitic cluster have an equally rigid ordering. However, Catalan allows freedom in the ordering of some pronominal clitics (Bonet, 1991: 67):

(6) **te** **'m** van recomanar
you.DAT/ACC me.ACC/DAT PAST recommend
per a aquesta feina
for to job
'they recommended me to you for this job' or
'they recommended you to me for this job'

Syntactic rules of ellipsis never apply to affixes. For example, in *Amali played baseball and Yasmin soccer*, the missing verb is understood through identity with the first verb, but the affix *–d* cannot similarly be recovered: **Amali danced the tango and Yasmin play soccer*. This holds true of most clitics, but recent evidence suggests that for some speakers at least, pronominal clitics in Serbo-Croatian may undergo ellipsis:

(7) ona **mu** ga je dala
she him.DAT it.ACC aux.3SG gave

a i ja **sam** **mu** ga dala
and also I AUX. 1.SG him. DAT it.ACC gave
'she gave it to him, and I did too'

Here both the pronominal clitic *mu* 'him' and the lexical verb *dala* 'gave' may undergo ellipsis (Franks and King, 2000: 336).

It is generally accepted that, if a morpheme comes between a stem and an affix, it must be itself an affix (Zwicky, 1977), yet Portuguese pronominal clitics appear between the verb stem and the tense-affix morpheme (Spencer, 1991: 366):

(8) levá **-lo** -ei
raise -it.ACC -aux.fut
'I will raise it'

In Portuguese, the lexical phonological rules treat the future ending like an inflectional affix, and it only appears on the verb. This may be related to the fact that historically the future ending was a clitic auxiliary that has become an affix (cf. French *j'aimerai* 'I will love'; see Spencer, 1991: Chap. 9).

The inability to bear accent or stress, a common feature of affixes, is not always a feature of clitics. In Bulgarian, the pronominal clitic *mu* 'him' bears stress (Hauge, 1976: 30):

(9) **ne** **mú** **li** **go** kaza?
not him.DAT Q it.ACC said.3.SG
'didn't he tell him it?'

The proclitic *ne* 'not' forms a prosodic word with the enclitic *mu* 'him' that bears stress. This word then serves as a host for both the question particle *li* and *go* 'it' (see Klavans, 1982, for further examples of accented clitics). Indeed, it has been suggested that some clitics do not require a host at all, for example, the Dutch prepositional *er* 'there' (Riemsdijk, 1978, 1999). For diagnostics for distinguishing clitics from affixes, see Zwicky and Pullum (1983); for the clitic versus word distinction, see Zwicky (1985).

For phonology and morphology, a principal interest is therefore in the definition of a word and the status of clitics. Some argue that there is a distinct category of clitic group within the prosodic hierarchy between the phonological word and the phonological phrase (Nespor and Vogel, 1986). Much recent prosodic literature rejects the need for a special category, some arguing that a given language may have more than one representation of its clitics and distinct treatments for proclitics and enclitics (see references in Gerlach and Grijzenhout, 2000: 2–8).

Typology of Clitics

The clitics in (1)–(3) appear in a subset of the set of positions in which their corresponding full forms appear (see Kaisse, 1985: 43 for a further discussion of English auxiliaries). In other words, they exhibit no distinct syntactic behavior; their position may be derived from the syntax. These are termed simple clitics in Zwicky (1977). In contrast, the pronominal clitics in examples (4)–(10) appear in a different syntactic position than their full-form equivalents. That is, whereas the clitic *l'* 'him' in the French example (10a) precedes the verb, the full form *lui* 'him' appears in the subcategorized argument position following the verb (10b). Clitics with such idiosyncratic syntax and phonological forms distinct from their full-form alternants are termed special clitics in Zwicky (1977). (A third distinction in Zwicky, 1977, that has not been widely adopted is the bound word, a clitic without any apparent full-form alternant, such as Latin *-que* 'and').

Special Clitics

The principal interest in special clitics and particularly pronominal clitics has been to account for their syntactic position and relation to the full-form positions. Kayne (1975) first argued that the relation was one of movement in French:

(10a) Jean **l'** aime *e*
John him.ACC loves
'John loves him'

(10b) Jean n' aime que lui
Jean NEG loves only him.ACC
'it's only him that Jean loves'

In (10a), the clitic is base-generated in argument position *e* and moved to its surface position. (10b) has the full-form alternant *lui* 'him' in the post-verbal argument position. Issues addressed within the movement approach include the questions of why the movement is generally clause-bound and why, in some Romance and Balkan languages, clitics associated with the argument structure of a subordinate

predicate may appear in the main clause (clitic climbing). Consider the Italian sentence:

(11) Piero **ti** verrà a parlare
Piero you.DAT come.FUT to speak.INF
di parapsicologia
of parapsychology
'Piero will come to speak to you about parapsychology'

Approaches have tended either to focus on the typology of movements (head vs. phrasal movement; A vs. A′ movement) or to argue that the structure in (11) is formally monoclausal in some way (see Rizzi, 1982, and articles in Riemsdijk, 1999). In Bare Phrase Structure (Chomsky, 1995), when a phrase dominates only a pronominal clitic, the clitic is formally both a maximal and minimal projection and thus able to move as either.

Clitic movement differs from more traditional examples of movement because the form of the moved element differs from that of the unmoved element. Also, in some South American Spanish dialects (Borer, 1984: 16), the clitic duplicates a phrase in argument position (called clitic doubling in Jaeggli, 1982):

(12) lo vimos a Juan.
him.ACC see.PRET.1.PL to Juan
'we saw Juan'

The clitic has been seen as absorbing the case and theta-assigning properties of the verb, forcing the need for a preposition (the Kayne-Jaeggli generalization; see Jaeggli, 1982; Borer 1984, 1986). However, there is no preposition in other cases of clitic doubling such as Macedonian example (4) (clitic doubling is common in the Balkan languages, Romanian, Greek, and Albanian, and in South Slavic; see articles in Riemsdijk, 1999; Beukema and Dikken, 2000). One recent reformulation suggests that the clitic is generated as part of the functional structure of the subcategorized phrase (e.g., as D) and moves independently of the overt phrase (e.g., Torrego, 1998).

Alternatively, pronominal clitics are argued to be base-generated in the surface position with an appropriate mechanism relating the clitic to the empty category in argument position (e.g., Borer, 1984; articles in Riemsdijk, 1999). With the rise of a more articulated functional hierarchy, a popular account has been to see clitics as agreement morphemes heading functional projections with arguments raising to check features (e.g., Sportiche, 1995).

Attempts to account for second-position clitics are many and varied, from the purely phonological treatment through to the purely syntactic. Increasingly, accounts involve a combination of components, such as modification of the syntactic output at the phonological or morphological form (either through movement or the selective spell-out of movement copies; see articles in Halpern and Zwicky, 1996; for variable spell-out in, mainly, Slavic, see Bošković, 2001).

Morphologists and Optimality theoretic approaches have often pursued clitics as phrasal affixes, usually with a wider cross-linguistic coverage. Klavans (1982, 1985) and Anderson (1992) position clitics via three parameters: (1) the choice of host as an initial or final element in a phrase (2) preceding or following the host, and (3) whether the item is proclitic or enclitic. Optimality theoretic approaches have proven particularly effective in capturing the various competing constraints with respect to clitic placement cross-linguistically (see Anderson, 1996; Franks and King, 2000; articles in Gerlach and Grizenhout, 2000).

For an introduction focusing on morphology, see Spencer (1991: Chap. 9); for significant reviews of the field and key approaches, see Borer (1986), Riemsdijk (1999), and Gerlach and Grizenhout (2000).

Clothing: Semiotics

M Danesi, University of Toronto, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Like any other object or artifact, we interpret 'clothes' as signs that stand for such things as the personality, the social status, and overall character of the wearer. This is why semioticians talk of 'dress codes' as particular types of social codes – systems of signs that cohere to provide information about how to dress for an occasion. Clothing is more than just bodily covering for protection. It is a sign system that is interconnected with the other sign systems of a society through which such emotions, states, and variables as attitudes, gender, age, social status, political beliefs, etc. can be encoded. This is why uniforms are required by special groups such as sports teams, military organizations, religious institutions, and the like. These encode specific kinds of meanings.

Since Roland Barthes' (1915–1980) study of fashion as a sign system in *Système de la mode* (1967), 'clothing semiotics,' as it is sometimes called, has become a popular area of inquiry both within semiotics (e.g., Rubinstein, 1995; Danesi, 2004) and in cognate disciplines such as anthropology and psychology (e.g., Davis, 1992; Enninger, 1993; Craik, 1993; Hollander, 1988, 1994; McRobbie, 1988; Steele, 1995; Luciano, 2000).

Bodies, Clothes, and Dress

People do not perceive bodies merely as biological substances; they are perceived also as signs of Selfhood (Goffman, 1959). For this reason, the human body has been subject to varying interpretations across history and across cultures. In ancient Greece, for example, the body was glorified as a source of pleasure; in ancient Rome, on the other hand, it was viewed as a source of moral corruption. The Christian church has always played on the duality of the body as a temple and as an enemy of the spirit.

Because clothes are worn on bodies, they are perceived as extensions of bodily meanings and are thus tied to varying cultural interpretation. This does not imply that clothes have basic social functions across societies. As the anthropologist Helen Fisher (1992: 253–254) observes, even in the jungle of Amazonia, Yanomamo men and women wear clothes for sexual

Clothing: Semiotics

M Danesi, University of Toronto, Toronto, Canada

Introduction

Like any other object or artifact, we interpret 'clothes' as signs that stand for such things as the personality, the social status, and overall character of the wearer. This is why semioticians talk of 'dress codes' as particular types of social codes – systems of signs that cohere to provide information about how to dress for an occasion. Clothing is more than just bodily covering for protection. It is a sign system that is interconnected with the other sign systems of a society through which such emotions, states, and variables as attitudes, gender, age, social status, political beliefs, etc. can be encoded. This is why uniforms are required by special groups such as sports teams, military organizations, religious institutions, and the like. These encode specific kinds of meanings.

Since Roland Barthes' (1915–1980) study of fashion as a sign system in *Système de la mode* (1967), 'clothing semiotics,' as it is sometimes called, has become a popular area of inquiry both within semiotics (e.g., Rubinstein, 1995; Danesi, 2004) and in cognate disciplines such as anthropology and psychology (e.g., Davis, 1992; Enninger, 1993; Craik, 1993; Hollander, 1988, 1994; McRobbie, 1988; Steele, 1995; Luciano, 2000).

Bodies, Clothes, and Dress

People do not perceive bodies merely as biological substances; they are perceived also as signs of Selfhood (Goffman, 1959). For this reason, the human body has been subject to varying interpretations across history and across cultures. In ancient Greece, for example, the body was glorified as a source of pleasure; in ancient Rome, on the other hand, it was viewed as a source of moral corruption. The Christian church has always played on the duality of the body as a temple and as an enemy of the spirit.

Because clothes are worn on bodies, they are perceived as extensions of bodily meanings and are thus tied to varying cultural interpretation. This does not imply that clothes have basic social functions across societies. As the anthropologist Helen Fisher (1992: 253–254) observes, even in the jungle of Amazonia, Yanomamo men and women wear clothes for sexual

modesty. A Yanomamo woman would feel as much discomfort and agony at removing her vaginal string belt as would a North American woman if one were to ask her to remove her underwear. Similarly, a Yanomamo man would feel just as much embarrassment at his penis accidentally falling out of its encasement, as would a North American male caught literally 'with his pants down.' As these cross-cultural comparisons bring out, clothing the body for social presentation is fundamentally a reflex of basic human functions. It is, in fact, intrinsically intertwined with sexual, romantic, and courtship functions throughout the world. When a young Zulu woman falls in love, she is expected to make a beaded necklace resembling a close-fitting collar with a flat panel attached, which she then gives to her boyfriend. Depending on the combination of colors and bead pattern, the necklace will convey a specific type of romantic message: e.g., a combination of pink and white beads in a certain pattern would convey the message *You are poor, but I love you just the same* (Dubin, 1987: 134).

At a biological level, clothes have a very important function indeed – they enhance survivability considerably. This is the level of denotation in semiotic theory – the level at which a referent is tied to its biological function. Clothes are, denotatively, human-made extensions of the body's protective resources, perceived as additions to our protective bodily hair and skin thickness. As Werner Enninger (1992: 215) aptly points out, this is why clothing styles vary according to geography: "The distribution of types of clothing in relation to different climatic zones and the variation in clothes worn with changes in weather conditions show their practical, protective function." But, it is also a fact that clothes take on a whole range of connotations in specific social settings that have little to do with survival. Connotations are meanings that accrue in cultural context over time, leading to the formation of 'dress codes' (from Old French *dresser* 'to arrange, set up') that inform people about how to clothe themselves in social situations. To someone who knows nothing about Amish culture, the blue or charcoal *Mutze* of the Amish male is just a jacket. But to the Amish the blue *Mutze* signals that the wearer is between 16 and 35 years of age, and the charcoal one signals that he is over 35. Similarly, to an outsider the Russian *kalbak* appears to be a brimless red hat. To a rural Russian, however, it means that the wearer is a medical doctor.

It is interesting to note, too, that dress codes, like other types of codes, can be used to lie about oneself. Con artists and criminals can dress in three-piece suits to look trustworthy, a crook can dress like a police officer to gain a victim's confidence, and so on. To discourage people from deceiving others through clothing, some societies have even enacted laws that prohibit misleading dressing, defining strictly who can dress in certain ways. In ancient Rome, for instance, only aristocrats were allowed to wear purple-colored clothes, and in many religiously oriented cultures, differentiated dress codes for males and females are regularly enforced.

Dress Codes

The broad range of connotations associated with dress codes is inextricably interconnected with social trends and political movements. Until the early 1950s, females in Western culture rarely wore pants. The one who 'wore the pants' in a family meant, denotatively and connotatively, that the wearer was a male. With the change in social role structures during the 1950s and 1960s, women began to wear pants regularly, sending out the new social messages that this entailed. The reverse situation has never transpired. Except in special ritualistic circumstances – such as the wearing of a Scottish kilt – men have never adopted wearing women's skirts in modern-day Western society. If they ever do, it would probably be labeled an act of 'transvestitism.'

Dressing for social reasons is a universal feature of human cultures. Even in cold climates, some people seem more interested in decorating their bodies than in protecting them. In the 1830s, British biologist Charles R. Darwin (1809–1882) traveled to the islands of Tierra del Fuego, off the southern tip of South America. There he saw people who wore only a little paint and a small cloak made of animal skin, in spite of the cold rain and the sleet. Darwin gave the people scarlet cloth, which they took and wrapped around their necks, rather than wear it around the lower body for warmth. Even in the cold weather, the people wore clothing more for decoration than for protection.

No one knows exactly why or when people first wore clothes. Estimates trace the origin of clothing to 100 000 years ago. Archeological research suggests that prehistoric hunters may have worn the skin of a bear or a reindeer in order to keep warm or as a sign of personal skill, bravery, and strength. By the end of the Old Stone Age – about 25 000 years ago – people had invented the needle, which enabled them to sew skins together. They had also learned to make yarn from the threadlike parts of some plants or from the fur or hair of some animals. In addition, they had learned to weave yarn into cloth. At the same time, people had begun to raise plants that gave them a steady supply of materials for making yarn. They had also started to herd sheep and other animals that gave them wool.

From the outset, it appears that clothes were worn not only for protection, but also for various social reasons. Shamans, for example, have always worn special clothing to indicate who they are. This continues to be the case for all kinds of clerics today. Dress also conveys people's beliefs, feelings, and general approach to life. Confident people often show more independence in choosing their style of dress than do those who are shy or unsure of themselves. The confident individual is likely to try new clothing styles. A shy person may seek security by following current styles. Others may be unconcerned about their dress and care little whether they dress in what others consider attractive clothing. Some people wear plain clothes because of strong beliefs about personal behavior. Such people believe it is wrong to care about wearing clothes as decoration. They believe that, instead, people should be concerned with other matters. Members of the Amish religious group have this kind of belief system. Amish men wear plain, dark clothes, and Amish women wear long, plain dresses. The hippies, on the other hand, dressed to emphasize 'love' and 'freedom' in the 1960s. Motorcycle gang members wear leather jackets, boots, and various items such as brass knuckles to convey toughness. Like language, a dress code can be endearing, offensive, controversial, delightful, disgusting, foolish, or charming.

In all societies, certain items of dress have special meanings. For example, the meanings of headgear vary widely, depending not only on climate, but also on customs. For instance, a Russian farmer wears a fur hat to protect himself from the cold. A South American cowboy wears a felt gaucho hat as part of his traditional costume. The American cowboy wears a wide-brimmed hat for protection from the sun. The members of a nation's armed services wear a hat as part of their uniform. The hats of coal miners, fire fighters, and matadors indicate the wearer's occupation. Clowns wear colorful, ridiculous hats to express fun and happiness. To the Amish, the width of the hat brim and the height of the crown can communicate whether the wearer is married or not.

It is interesting to note that throughout the centuries, the desire of people to be fashionable has resulted in many kinds of unusual hats. During the 1400s, many European women wore a tall, cone-shaped hat called a *hennin*. This hat measured from 3 to 4 feet (0.9 to 1.2 meters) high and had a long, floating veil. The Gainsborough hat became popular with both men and women in the late 1700s. It had a wide brim and was decorated with feathers and ribbons. Hats are, and have always been, props in dress codes, communicating various things about the people who wear them. Most people wear a hat that they believe makes them look attractive. This is why much protective headgear today, such as fur hoods and rain hats, is both attractive and stylish. Even the caps of police officers and military personnel are designed to improve the wearer's appearance.

No one knows when people first wore hats. People in various cold climates may have worn fur hoods as far back as 100 000 years ago. Through the centuries, people have worn headgear to indicate their social status. In ancient Egypt, the nobility wore crowns as early as 3100 B.C. They have also worn them to be fashionable. Some ancient Greeks wore hats known as *pelos* for fashion. These were usually made from wool fibers. Pelos can still be found in parts of southern Siberia today. They are similar to the brimless, tasseled hat known as a *fez*. By the 14th century, people wore hats increasingly for fashion, resulting in the development of a large variety of hats and frequent changes in hat styles. People in one area often adopted the hat styles worn in another. During that century, for example, women in western Europe wore a type of hat that resembled a turban. They adopted this style from the headgear worn by people who lived in the Middle East and the Orient. During the 20th century, hat styles varied more widely than ever before. In the 1920s, women wore a drooping, bell-shaped hat called the *cloche*. In the 1930s, they wore the harlequin hat, which had a wide, upturned brim. A variety of hats were worn in the 1940s and 1950s. The cap became a central accouterment of male teen style, during the heyday of the rap movement in the mid to late 1990s, when it symbolized clique solidarity.

Nudity

The human being is the only animal that does not 'go nude,' so to speak, without social repercussions (unless, of course, the social ambiance is that of a nudist camp). Nudity is the counterpart of clothing, and thus can only be interpreted culturally. What is considered 'exposable' of the body will vary significantly from culture to culture, even though the covering of genitalia seems, for the most part, to cross cultural boundaries.

Semiotically, nudity assumes significance because it is in binary opposition with clothing – i.e., it forms a counterpart to it, with one entailing the other. Acts of 'clothing-removal,' such as strip-tease performances, have appeal because of this unconscious semiotic dualism. In an audience setting, these have, first and foremost, something of a pagan ritualistic quality to them, based on mimetic portrayals of sexual activities and sexual emotions. As the psychoanalyst Sigmund Freud (1856–1939) suggested in many of his writings,

clothing the body has, paradoxically, stimulated curiosity and desire for the nude body. In a word, what makes nudity appealing in such situations is clothing. This is why certain types of clothing items, such as shoes, are perceived to have sexual significance. They allude to bodily parts that have become desirable, engaging viewers in a communal ritual similar to the many carnivals put on throughout the world.

The nude body is, thus, a sign. This is why visual artists have always had a fascination with the nude figure. The ancient Greek and Roman nude statues of male warriors, Michelangelo's (1475–1564) powerful *David* sculpture, Rodin's (1840–1917) nude sculpture *The Thinker* are all suggestive of the potency of the male body. It is this 'iconography' of nudity that enhances the attractiveness of the male in our society. A male with a 'weakling' body is hardly ever perceived as sexually attractive. On the other side of this semiotic paradigm, paintings and sculptures of female nude figures have tended to portray the female body ambiguously as either (1) soft and submissive, as can be seen in the famous ancient Greek statue known as the Venus de Milo, which represents Aphrodite, the Greek goddess of love and beauty (Venus in Roman mythology), or (2) feral and powerful (as can be seen in the sculptures of Diana of Greek mythology). It is (2) that came to the forefront again in the 1990s. Known as the 'girl power' movement, representations of women in pop culture now emphasize the second type of the two iconographic traditions.

The interplay between clothing and nudity as sign systems is part of a culture's historical iconography. This is largely unconscious, conditioning representations of bodies in virtually all areas of human social life, from advertising and erotica to religious dress.

Fashion

Until the Renaissance, following trends in dress, known as 'fashion,' was the privilege of the rich in most parts of the world. Since the early decades of the 20th century, however, it has become an intrinsic component of the lifestyle of common people in many parts of the world. 'Fashion statement' has become personal statement.

Fashion can be defined as the prevailing style or custom of dress. Although fashion usually refers to dress, it does not mean the same thing as clothing. People have always worn clothes that reflected the long-standing customs of their communities, and clothing styles changed extremely slowly in the past. Fashion, however, causes styles to change rapidly for a variety of historical, psychological, and sociological reasons. A clothing style may be introduced as a fashion, but the style becomes a custom if it is handed down from generation to generation. A fashion that quickly comes and goes is called a fad. As Barthes (1967) argued, it constitutes a kind of 'macro' dress code that sets standards according to age, gender, class, etc. To understand how fashion codes emerge, it is instructive to consider the male business suit. The connotative message underlying the apparel text is, of course, 'dress for success.' How did this subtext crystallize in our culture? A look at the history of the business suit provides an interesting answer to this question.

In 17th-century England, there existed a bitter conflict in social ideology between two forces – the Royalist 'Cavaliers,' who were faithful to King Charles I, and the Puritans, who were followers of Oliver Cromwell (1599–1658), the military, political, and religious figure who led the Parliamentarian victory in the English Civil War (1642–1649). This conflict was a battle of lifestyles, as the two warring camps sought to gain political, religious, and cultural control of English society. The Cavaliers were aristocrats who only superficially followed the teachings of the Anglican Church. Their main penchant was for a life of indulgence (at least as the Puritans perceived it). They wore colorful clothes, flamboyant feathered hats, beards, and long flowing hair. This image of the Cavalier as a 'swashbuckler' has been immortalized by literary works such as *The Three Musketeers* (Alexandre Dumas, 1844) and *Cyrano de Bergerac* (Edmond Rostand, 1897). The Puritans, on the other hand, frowned precisely upon this type of fashion, because of the 'degenerate lifestyle' that they perceived it to represent. Known as the 'Roundheads,' Cromwell's followers cropped their hair very short, forbade all carnal pleasures, and prohibited the wearing of frivolous clothing. They wore dark suits and dresses with white shirts and collars. Their clothes conveyed sobriety, plainness, and rigid moralism.

The Cavaliers were in power throughout the 1620s and the 1630s. During this period the Puritans escaped from England and emigrated to America, bringing with them their lifestyle, rigid codes of conduct, and clothing styles. In 1645 the Puritans, led by Cromwell, defeated the Royalist forces and executed the king. Subsequently, many Cavaliers also emigrated to America. Since the Puritans had set up colonies in the northeast, the Cavaliers decided to set up colonies in the south. The king's son, Charles II, escaped to France to set up a court in exile. For a decade, England was ruled by the Puritans. Frowning upon all sorts of pleasure-seeking recreations, they closed down theaters, censored books, enforced Sunday laws, and forbade the wearing of flashy clothing.

With Cromwell's death in 1658, the Puritans were eventually thrown out of power and England

welcomed the exiled king, Charles II, back in 1660. Known as the Restoration, the subsequent 25-year period saw a return to the lifestyle and fashions of the Cavaliers. For two centuries the Puritans had to bide their time. They were excluded from holding political office, from attending a university, from engaging in any socially vital enterprise. Nevertheless, throughout the years they maintained their severe lifestyle and dress codes.

By the time of the Industrial Revolution, the Puritans had their final and lasting revenge. Their lifestyle – based on thrift, diligence, temperance, and industriousness, which some have called the 'Protestant work ethic' – allowed them to take advantage of the economic conditions in the new industrialized world. In America and in England, Cromwell's descendants became rich and eventually took over the reigns of economic power. Ever since, Puritan ethics and fashion in the work force have influenced British and North American business culture, not to mention social mores and values at large. The origins of modern corporate capitalism are to be found in those values. The belief that hard work and 'clean living' are necessarily interrelated, and that this combination leads to wealth and prosperity, had become a widespread one by the turn of the present century. To this day, there is a deeply felt conviction in capitalist culture that hard work and strict living codes will lead to success in both this life and the afterlife.

The business suit is a contemporary version of Puritan dress. The toned down colors (blues, browns, grays) that the business world demands are the contemporary reflexes of the Puritan's fear and dislike of color and ornament. During the 'hippie' 1960s and early 1970s, the office scene came briefly under the influence of a new form of Cavalierism, with the wearing of colorful suits, turtle neck sweaters rather than white shirts, longer hair, sideburns, Nehru jackets, medallions, and beards. This new 'fashion dare' made a serious pitch to take over the world of corporate capitalism. But it was bound to fail, as the hippie movement of the 1960s was defeated and subsequently overtaken by conservative neo-puritanical forces in the late 1970s and 1980s. The 'business suit' model became once again the dress code for all of corporate North America, with only minor variations in detail.

The business suit somehow endures – perhaps because it is intrinsically intertwined with the history of capitalism. But, nowadays, even this fashion code has become rather eclectic, not to say fragmented. Take, for example, the length of the skirt in the female business suit code. The mini, maxi, and normal length skirts are alternatively in and out of fashion. Evidently, a detail such as length of skirt is, in itself, meaningless. What appears to count is what it implies as a signifier about the ever-fluctuating perceptions of women in the workplace and in society at large. When the mini is 'in,' it might imply an increased emphasis on sexual freedom in the culture. When it is 'out,' then it might imply the opposite – a decreased emphasis on sexuality. Whatever the case may be, the point to be made here is that the specific elements and features of a fashion code will invariably have connotative value that is a derivative of larger social codes within the culture.

True fashions began to appear in northern Europe and Italy when a system of social classes developed in the late Middle Ages with the rise of the bourgeois class. At this time, the people of Europe began to classify one another into groups based on such factors as wealth, ancestry, and occupation. The clothes people wore helped identify them as members of a particular social class. Before the late Middle Ages, only wealthy and powerful individuals concerned themselves with the style of their clothes. But when the class system developed, the general population began to compete for positions within society. Fashion was one means by which people did this. One of the first true fashions appeared among young bourgeois Italian men during the Renaissance. While their elders dressed in long traditional robes, the young males wore tights and short, close-fitting jackets called doublets. The was one of the first examples of youth-based clothing that intentionally set itself apart from the adult dress code. German soldiers set another early fashion when they slashed their luxurious silk clothes with knives to reveal another colorful garment underneath. Theirs too was a youth-based fashion trend, probably intended to influence their appeal to the opposite sex.

Before the 1800s, many countries controlled fashion with regulations called sumptuary laws. These limited the amount of money people could spend on private luxuries, being obviously designed to preserve divisions among the classes. They thus regulated fashion according to a person's rank in society. In some countries, only the ruling class could legally wear silk, fur, and the colors red and purple. In Paris in the 1300s, middle-class women were forbidden by law to wear high headdresses, wide sleeves, and fur trimmings. Other sumptuary laws forced people to buy products manufactured in their own country to help the country's economy. For example, an English law in the 1700s prohibited people of all classes from wearing cotton cloth produced outside of England. But the lure of fashion caused many people to break this law. The cloth was so popular that people risked arrest to wear it.

Ordinary people have always hoped to raise their social position by following the fashions of privileged

people. Fashions have also emerged to accompany differing perceptions of gender. Until the late 1700s, upper-class European men dressed as elaborately as women did. It was acceptable for men to wear bright-colored or pastel suits trimmed with gold and lace, hats decorated with feathers, high-heeled shoes, and fancy jewelry. But by the mid-1800s, men had abandoned such flamboyance in favor of plain, dark-colored wool suits. Society came to view this new fashion style as democratic, businesslike, and masculine. Until the early 1900s, European and American women rarely wore trousers, and their skirts almost always covered their ankles. By the 1920s, however, standards of feminine modesty had changed to the point that women began to wear both trousers and shorter skirts.

Contrary to popular belief, political events seldom cause fashions to change. However, political events do sometimes speed up changes that have already begun, as we saw in the case of the business suit. For example, during the French Revolution (1789–1799), simple clothing replaced the extravagant costumes made fashionable by French aristocrats. But simple styles had become popular years earlier when men in England started wearing practical, dark suits instead of elegant, colorful clothes. English people identified these plain suits with political and personal liberty. Because many French people admired English liberty, this style was already becoming fashionable in France before the revolution.

In the 19th century, the invention of mechanical looms, chemical dyes, artificial fabrics, and methods of mass production made fashions affordable to many more people. In addition, new means of mass communication spread European and American fashions throughout the rest of the world. The Industrial Revolution created a 'fashion global village.' Since then, fashion shows and fashion magazines have proliferated. And, as Barthes (1967) pointed out, they change constantly because rapid turnover guarantees economic success. It is the only constant in contemporary fashion trends.

Conclusion

Like all social codes, clothing is interconnected with the other codes of a culture. For instance, it is intertwined with religious ceremonies and rituals – the clothing worn at a religious service, during certain religious feasts and festivals, for example, is designed to send out specific kinds of religious messages. It is also intertwined with daily life routines, whereby dress codes guide or are sensitive to lifestyle and social options. The semiotic study of clothing thus shows that clothing is a sign system. This is why, arguably, people are so interested in fashion trends (Steele, 1995).

Today, attractive-looking celebrities, rather than aristocrats, set trends. People tend to follow fashion primarily to make themselves similarly attractive. When the standard of beauty changes, fashion changes with it. For example, when physical fitness became a popular standard of good looks in the 1980s, people began to wear exercise and athletic clothing more often. A clothing style may become fashionable over time with many different groups. For example, people began wearing blue jeans during the mid-1800s as ordinary work clothes. For decades, they were worn chiefly by outdoor laborers, such as farmers and cowboys. In the 1940s and 1950s, American teenagers adopted blue jeans as a comfortable, casual youth fashion. Young people during the 1960s wore blue jeans as a symbol of rebellious political and social beliefs. By the 1970s, people no longer considered jeans rebellious, and expensive designer jeans had become fashionable.

In a fundamental sense, culture can be characterized as a huge system of connotative meanings that cohere into a 'macro-code' that allows members of the culture to interact purposefully and to represent and think about the world in specific ways. This is why some semioticians prefer to call it the 'semiosphere,' a term coined by the great Estonian semiotician Juri Lotman (1922–1993). In biology, a region that sustains life is called the 'biosphere.' By analogy, the semiosphere is the region of social life that sustains knowledge-making and representational activities (Lotman, 1991). Clothing is one of those sign systems that provides a direct route to the study of the semiosphere.

Coarticulation

W Hardcastle, Queen Margaret University College, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

A stretch of speech is often represented in terms of discrete elements (phonemes, segments, letters, etc.) arranged in a linear sequence on the page. However, when the movements of speech organs that produce this stretch of speech, such as the tongue, lips, and soft palate, are tracked instrumentally, it can be seen that these organs are continuously moving and that movements associated with different segments overlap in time. A consequence of this dynamic overlapping is that there is virtually no one-to-one correspondence between aspects of the speech signal and the discrete units of representation. The attempt to reconcile abstract elements in the phonological representation, which are discrete and timeless, with the time-varying physiological realizations as articulatory movements (and their acoustic consequences) has remained one of the central issues in modern experimental phonetics and has led to the development of many different theories and models.

The ubiquitous overlapping of articulatory movements associated with separate sound segments is referred to as coarticulation. The term appears to have originated in the 1930s with Menzerath and de Lacerda (1933), building on the work of early experimental phoneticians such as Scripture, Rousselot, and Laclotte. In demonstrating that speech organs are continuously moving and overlapping in time, these early investigators argued against a prevailing view of their time that speech consisted of a series of relatively steady-state postures of the speech organs, linked by rapid transitional glides. Scripture, for example, concluded that "the tongue is never still and never occupies exactly the same position for any period of time" (Scripture, 1902: 325). In addition, he established that the character of any articulatory speech movement depends on other movements occurring at the same time: thus there are no static characteristic postures. (For discussions of the early history of coarticulation, see Hardcastle, 1981 and Kühnert and Nolan, 1999.)

One of the consequences of coarticulation is that speech sounds vary (both physiologically and acoustically) according to the nature of neighboring sounds, and 'coarticulation' is often used these days in its broader sense to refer to this variation. Since the 1960s, coarticulation has developed into a major area of phonetic research, and many theories have been devised to account for coarticulatory effects. The volume edited by Hardcastle and Hewlett (1999) offers a comprehensive overview of theories, data, and experimental techniques pertaining to coarticulation. Other critical reviews of models and theories of coarticulation can be found in Farnetani (1990; 1997), Kent and Minifie (1977), Sharf and Ohde (1981), Kent (1983), and Fowler (1985).

The phenomenon of coarticulation can be illustrated by a graphical representation of movements of the speech organs (and different parts of the same organ) (see **Figure 1**). **Figure 1** shows an instrumental record of movements of the jaw, lips, and tongue (tip and dorsum) during production of the sentence "say schooner again" by a Scottish English speaker. This speaker rounds the vowel [u] in the word 'schooner,' and the rounding is indicated in the instrumental record by horizontal protrusion of the lower lip. The lower lip is seen to be protruding (marked as a downward direction of the lip trace) well before the [u] vowel is articulated, in fact as early as the beginning of the [s] (indicated by the fricative noise on the speech waveform and the increase in anterior contact on the EPG trace).

Coarticulation

W Hardcastle, Queen Margaret University College, Edinburgh, UK

A stretch of speech is often represented in terms of discrete elements (phonemes, segments, letters, etc.) arranged in a linear sequence on the page. However, when the movements of speech organs that produce this stretch of speech, such as the tongue, lips, and soft palate, are tracked instrumentally, it can be seen that these organs are continuously moving and that movements associated with different segments overlap in time. A consequence of this dynamic overlapping is that there is virtually no one-to-one correspondence between aspects of the speech signal and the discrete units of representation. The attempt to reconcile abstract elements in the phonological representation, which are discrete and timeless, with the time-varying physiological realizations as articulatory movements (and their acoustic consequences) has remained one of the central issues in modern experimental phonetics and has led to the development of many different theories and models.

The ubiquitous overlapping of articulatory movements associated with separate sound segments is referred to as coarticulation. The term appears to have originated in the 1930s with Menzerath and de Lacerda (1933), building on the work of early experimental phoneticians such as Scripture, Rousselot, and Laclotte. In demonstrating that speech organs are continuously moving and overlapping in time, these early investigators argued against a prevailing view of their time that speech consisted of a series of relatively steady-state postures of the speech organs, linked by rapid transitional glides. Scripture, for example, concluded that "the tongue is never still and never occupies exactly the same position for any period of time" (Scripture, 1902: 325). In addition, he established that the character of any articulatory speech movement depends on other movements occurring at the same time: thus there are no static characteristic postures. (For discussions of the early history of coarticulation, see Hardcastle, 1981 and Kühnert and Nolan, 1999.)

One of the consequences of coarticulation is that speech sounds vary (both physiologically and acoustically) according to the nature of neighboring sounds, and 'coarticulation' is often used these days in its broader sense to refer to this variation. Since the 1960s, coarticulation has developed into a major area of phonetic research, and many theories have been devised to account for coarticulatory effects. The volume edited by Hardcastle and Hewlett (1999) offers a comprehensive overview of theories, data, and experimental techniques pertaining to coarticulation. Other critical reviews of models and theories of coarticulation can be found in Farnetani (1990; 1997), Kent and Minifie (1977), Sharf and Ohde (1981), Kent (1983), and Fowler (1985).

The phenomenon of coarticulation can be illustrated by a graphical representation of movements of the speech organs (and different parts of the same organ) (see **Figure 1**). **Figure 1** shows an instrumental record of movements of the jaw, lips, and tongue (tip and dorsum) during production of the sentence "say schooner again" by a Scottish English speaker. This speaker rounds the vowel [u] in the word 'schooner,' and the rounding is indicated in the instrumental record by horizontal protrusion of the lower lip. The lower lip is seen to be protruding (marked as a downward direction of the lip trace) well before the [u] vowel is articulated, in fact as early as the beginning of the [s] (indicated by the fricative noise on the speech waveform and the increase in anterior contact on the EPG trace).

Figure 1 Computer printout of instrumental records of the sentence ''say schooner again'' spoken by a speaker of Scottish English. The top trace shows the speech waveform and time scale in tenths of seconds. The next four traces show kinematic data from a Carsten's electromagnetic articulograph (EMA), which plots movement in the x-y plane of miniature coils attached to the midline of articulatory structures. The EMA traces are, from the top: vertical up-down movement of the jaw; horizontal front-back movement of the lower lip (negative = forward); vertical up-down movement of the tongue dorsum; and velocity of tongue dorsum movement. The lower traces show information from electropalatography synchronized with EMA: total tongue–palate contacts activated in the anterior region of the palate (ANT trace) and total number activated in the posterior region of the palate (PST trace). Reprinted from Durward B, Baer G & Rowe P (eds.) (1999). *Functional Human Movement: Measurement and Analysis*. Oxford, UK: Butterworth Heinemann.

It reaches its maximum forward movement during the articulatory closure for the [k] (indicated by maximum raising of the tongue dorsum trace). The illustration in Figure 1 shows an example of labial coarticulation with the lips moving forward in anticipation of the rounded vowel at the same time as the tongue articulation for the [s]. The [s] in this environment would therefore be different from the [s] in a word such as 'skill,' in which no such lip rounding would be involved. Similar contextual effects involving other articulations can be seen in the [k] in 'key,' which is produced farther forward in the oral cavity than the [k] in 'car' because the body of the tongue is anticipating the more fronted position required for the [i] vowel. Another example is the difference between the vowel sounds in 'mad' versus 'bad.' The vowel in 'mad' will usually be more nasalized than that in 'bad' because the soft palate lowering for the [m] in 'mad' coarticulates or overlaps with the tongue movement for the vowel, unlike in 'bad.'

The term 'coarticulation' in its broadest sense is often used interchangeably with 'assimilation,' which also refers to the influence of context on speech sounds. Thus, we find *place* assimilation in words like 'meat pie,' in which the alveolar stop [t] 'assimilates' into the place of articulation of the following bilabial [p], or *voice* assimilation in a phrase such as 'I have to,' in which the voicing of the [v] assimilates into the following voiceless stop [t] and becomes the perceived voiceless [f]. Some investigators (including the originator of the term, P. Menzerath) restrict 'coarticulation' to the physiological mechanisms underlying speech production and reserve 'assimilation' for audible change to specific sounds in context, often resulting in perception of a different phoneme.

Coarticulatory effects such as those above can be described in terms of their type and extent. Type may refer to the speech organs predominantly involved, e.g., labial coarticulation (or more specifically, lingual/labial), nasal coarticulation, etc. Type may also refer to the direction of coarticulatory influence, whether anticipatory (sometimes called 'right-to-left') or perseverative (carryover, or 'left-to-right'). Designation of coarticulatory influences as anticipatory or carryover depends on the theoretical premise that there is an underlying linear abstract segmental representation at some level in the speech production process. Thus, anticipatory coarticulation occurs if a sound segment is influenced by (or even becomes more like) a following sound (such as in the 'schooner' example in Figure 1). If a sound shows influence of a preceding sound, this is an example of carryover or perseverative coarticulation.

Some theories claim that carryover coarticulation occurs because of inherent physiological characteristics of the speech articulators. For example, in the word 'mad,' coarticulated nasality is said to occur on the vowel because the soft palate is relatively slow moving and takes time to rise from its maximally lowered position for [m]. Anticipatory coarticulation is rather more difficult to explain. At one level it can be seen as a production strategy to enable articulatory movements to occur at the rate necessary to deliver up to five syllables per second, as in normal spontaneous speech. It is also probably the most economical strategy to employ, particularly in the face of increasing demands that occur in fast colloquial speech, and the concept of 'economy of effort' has frequently been linked to coarticulation. (For further discussion of competing demands on the articulators during a communication situation, see Lindblom, 1990). For rapid productions, some degree of parallel processing is inevitable and is seen also in the skeletal motor system (such as in sign language interpreters engaged in rapid finger spelling). At the cognitive level, anticipatory coarticulation can be seen as a further example of the universal tendency for the brain to 'scan ahead of time' (cf. early work on the serial ordering of behavior by Lashley, 1951). There may also be some perceptual motivation for anticipatory coarticulation. For example, as a result of anticipatory coarticulation, acoustic information on an upcoming segment is available to the listeners before that segment is articulated, and this prior knowledge may facilitate more accurate perception than would be the case if all acoustic cues were confined within the temporal boundaries of that segment (Kühnert and Nolan, 1999).

Coarticulation can also be described with reference to the temporal domain of its influence. This can be expressed in terms of time or as numbers of segments. In the example in Figure 1, the labial coarticulatory influence extended two segments in advance of the vowel. Some early theories of anticipatory coarticulation claimed that articulations began as early as possible (e.g., a study by Benguerel and Cowan, 1974, showed lip rounding influence extending up to six segments in advance). Other models using the notion of distinctive features involved a 'feature-spreading' approach following Henke's work (1966) on computer modeling. For example, the feature [+ rounding] spreads across all [-rounded] segments in a string. An earlier influential theory (Kozhevnikov and Chistovich, 1965) proposed a higher-level structure, the articulatory syllable, defined with reference to the temporal domain of coarticulatory spread. Based on measurements of lip protrusion for the vowel [u], the model stated that this protrusion begins at the same time as the first consonant in any string of consonants preceding the vowel, providing these consonants did not involve 'contradictory' articulatory gestures. Later work was to show, however, that coarticulatory influences could in fact extend across articulatory syllable boundaries so that in a vowel-consonant-vowel sequence, for example, the two vowels influence each other across a consonant boundary, a result not predicted by Kozhevnikov and Chistovich's model (see, for example, Öhman, 1966, and for the many studies since, see the review in Farnetani and Recasens, 1999).

These early theories proposed that coarticulation begins as early as possible. An alternative view is that coarticulatory influences are time locked and that the component gestures of a segment begin at a fixed interval before the phonetic target is achieved (see, e.g., Bell-Berti and Harris, 1982). Closely related to the idea of time locking is a radical approach to the phenomenon of coarticulation based on action theory using the concept of coordinative structures (see e.g., Kelso *et al.*, 1986). In this approach the underlying units of speech production are not segment-like units such as is assumed in most of the above accounts but 'gestures,' which are speech-relevant goals containing spatial-temporal information about speech articulations. An example of an articulatory gesture in this framework would be a bilabial closure, which involves a specific and unique combination of coordinated upper lip, lower lip, and jaw movements regardless of the context. Contextual effects are said to arise as a result of temporal overlapping ('coproduction') with other gestures. In this coordinative structure framework, coarticulation is viewed as an automatic consequence of the inherent kinematic properties of the production mechanism. (For discussions of the gestural approach and its formulation in the articulatory phonology framework,

see Browman and Goldstein, 1992, Fowler and Saltzman, 1993, and Nolan, 1982.)

Much research has been devoted to identifying the types of constraints that affect coarticulatory processes. The notion of 'coarticulatory resistance' (Bladon and Al-Bamerni, 1976; Recasens, 1985) attempts to identify some of the articulatory characteristics that may affect the spread of coarticulatory influences. There is evidence that coarticulation is gradual and varies between different segments. Recasens (1991, 2002) has developed an articulatory constraint model that relates coarticulatory resistance to the degree of tongue dorsum raising required for the consonant. Other constraints on coarticulatory processes pertain to prosodic and related aspects of the language, such as stress patterns, suprasegmental boundaries, syntactic structures, rate of articulation, clarity, and speech style (see, e.g., Engstrand, 1988; Lindblom, 1963; Hardcastle, 1985; and Matthies *et al.*, 2001), and all these factors have been found to influence coarticulation both temporally and spatially. The phonological structure of a particular language may also constrain coarticulatory patterns. For example, there is some evidence that the extent of coarticulatory nasalization of vowels preceding a nasal consonant will tend to be more restricted in those languages that have a nasal/oral phonological contrast in vowels (e.g., French) compared with those that do not (e.g., English; see, e.g., Clumeck, 1976). Various models have attempted to account for these language-specific influences (see, for example, the 'window model of coarticulation' of Keating, 1990, and for a comprehensive account of crosslanguage studies of coarticulation, see Manuel, 1999).

Coarticulation remains a productive area of phonetic research, and we can expect to see more-refined models being developed as instrumental techniques for investigating the kinematics of speech production improve.

William Cobbett, essayist, politician, agriculturist, and grammarian, was born in Farnham, Surrey, England, on March 9, 1763. Cobbett grew up as a farm boy with virtually no formal education. In 1784, at the age of 21, he joined the army, where he managed to find time to teach himself the rules of grammar by reading and copying Robert Lowth's *A short introduction to English grammar* (1762). One day he received an eloquent but ungrammatical letter from a Nottingham stocking weaver, which impelled him

Cobbett, William (1763–1835)

M Miyawaki, Senshu University, Kanagawa, Japan

© 2006 Elsevier Ltd. All rights reserved.

William Cobbett, essayist, politician, agriculturist, and grammarian, was born in Farnham, Surrey, England, on March 9, 1763. Cobbett grew up as a farm boy with virtually no formal education. In 1784, at the age of 21, he joined the army, where he managed to find time to teach himself the rules of grammar by reading and copying Robert Lowth's *A short introduction to English grammar* (1762). One day he received an eloquent but ungrammatical letter from a Nottingham stocking weaver, which impelled him

to write an English grammar. His *Grammar of the English language*, set out in the form of letters to his son James, first appeared in New York in 1818. It was an immediate success. The second and third editions were published in London in 1819, and the fourth edition followed in 1820. A revised edition, to which were added "Six lessons, intended to prevent statesmen from using false grammar, and from writing in an awkward manner," appeared in 1823. In 1832 Cobbett was elected an M.P. representing Oldham, Lancashire, in which seat he remained until his death on June 18, 1835.

Although the overall framework of Cobbett's grammar is traditional, being based on the nine parts of speech and their categories, the readership he has in mind is unique. As the subtitle indicates, his grammar is "intended for the Use of Schools and of Young Persons in general; but, more especially for the Use of Soldiers, Sailors, Apprentices, and Ploughboys." Thus Cobbett's aim was to make young people of the working class competent speakers and writers of English so that they would be able to "assert with effect [their] rights and liberties" (edn. by Nickerson and Osborne, 1983: 32). Accordingly, his statements are prescriptive rather than descriptive, with reason as the criterion of correctness: "It is *reason* [that] is to be your sole guide" (93). Cobbett warned against the use of *me* in "It was *me,*" which should be "It was *I*" (93). Similarly, he criticized the double negative in "Do *not* give him *none* of your money," which should be "Do *not* give him *any* of your money" (141). Cobbett also advised on matters of style, emphasizing the clearness and strength of meaning. He warned that "one of the greatest of all faults in writing and in speaking is [...] the using of many words to *say little*" (150). Thus his grammar can be seen as a forerunner of such manuals of usage and style as H. W. Fowler's *Modern English usage* (1926).

Cocos (Keeling) Islands: Language Situation

U Ansaldo, Universteit van Amsterdam, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

The Cocos (Keeling) Islands are a coral atoll of 27 islands that constitute the westernmost outpost of Australia, positioned in the middle of the Indian Ocean 1000 km southwest of Java. First settled by agents of the East India Company, in 1829 the original population consisted of a total of 98 people, most of whom were of Indonesian/Malay origin, with a few British sailors as well as, possibly, a few individuals of Papuan, Indian, and even Asian provenance. They were portrayed as speaking a form of Trade Malay or a Malay-based *lingua franca*.

As of 2001, the population of the Cocos-Keeling consists of 618 individuals who reside on the two inhabited islands of the atoll. West Island is the base for roughly 100 Australians, mostly administrators and schoolteachers on 2- to 3-year postings. They speak Australian English and, with few exceptions, have no knowledge of Malay. Home Island, the original settlement of the first settlers, still houses 80% of the population, predominantly of Indonesian provenance. These are the Cocos Malays, descendants of laborers brought to the islands during the 150-year period in which the islands were an estate of the Clunies-Ross clan, which lasted until the Australian government took over in 1978. The community is Muslim.

Cocos Malay is the dominant language on Home Island; it can be described as a contact variety of colloquial Malay with strong Javanese influences. It was the dominant language until Australian takeover and is still very alive today. Knowledge of English is restricted in most individuals of advanced age; it is functional in most individuals of middle age, and the younger generations have near-to-native fluency. The school operates a bilingual program in which English is the language of immersion and Cocos Malay is also used to aid in instruction, particularly at primary

The Cocos (Keeling) Islands are a coral atoll of 27 islands that constitute the westernmost outpost of Australia, positioned in the middle of the Indian Ocean 1000 km southwest of Java. First settled by agents of the East India Company, in 1829 the original population consisted of a total of 98 people, most of whom were of Indonesian/Malay origin, with a few British sailors as well as, possibly, a few individuals of Papuan, Indian, and even Asian provenance. They were portrayed as speaking a form of Trade Malay or a Malay-based *lingua franca*.

As of 2001, the population of the Cocos-Keeling consists of 618 individuals who reside on the two inhabited islands of the atoll. West Island is the base for roughly 100 Australians, mostly administrators and schoolteachers on 2- to 3-year postings. They speak Australian English and, with few exceptions, have no knowledge of Malay. Home Island, the original settlement of the first settlers, still houses 80% of the population, predominantly of Indonesian provenance. These are the Cocos Malays, descendants of laborers brought to the islands during the 150-year period in which the islands were an estate of the Clunies-Ross clan, which lasted until the Australian government took over in 1978. The community is Muslim.

Cocos Malay is the dominant language on Home Island; it can be described as a contact variety of colloquial Malay with strong Javanese influences. It was the dominant language until Australian takeover and is still very alive today. Knowledge of English is restricted in most individuals of advanced age; it is functional in most individuals of middle age, and the younger generations have near-to-native fluency. The school operates a bilingual program in which English is the language of immersion and Cocos Malay is also used to aid in instruction, particularly at primary

level. Code-switching is common in the young generation. This generation is also particularly exposed to standard Indonesian and standard Malay. The exposure to Indonesian comes from the media (Indonesian TV) as well as from Bahasa Indonesia, which is offered in school as a second language choice. The influence of Malay comes less directly, from the status that the language enjoys for literary and religious reasons: in 2001 there were clearly normative voices to be heard advocating a more standard form of Malay to be spoken on the island. All these facts considered, it is quite likely that Cocos Malay may lose many of its particular traits in the near future.

Cocos Malay communities can also be found in Western Australia (children have to move there to complete their education after grade 10) as well as in Sabah, Malaysia. Relocated from the original settlements in different waves as the islands can only sustain a limited population, these communities are described as having lower proficiency in Cocos Malay than that on Home Island. In particular, in Sabah it is reported that convergence towards standard Malay has taken place.

Codes, Elaborated and Restricted (Bernstein)

A Capone, Barcellona, Italy

© 2006 Elsevier Ltd. All rights reserved.

Bernstein was among the first scholars to focus on the correlation between the scholastic success (or failure) of a learner and the social class he or she belonged to. A student living in a well-off family, having many cultural stimuli (books, newspapers, periodicals, films, etc.) is bound to develop a rich and fully articulated language (a so-called 'elaborate code'), whereas a student who belongs to a working-class family and is exposed to poor linguistic and cultural stimuli, develops a fragmented, poor, syntactically deficient language (called a 'restricted code' by Bernstein) (see Bernstein, 1971–1975).

Contrary to the Chomskyan theory that language naturally develops in the brain, due to the interaction of biologically innate structures and the environment to which the child is exposed, may be that the data to which the child is exposed are so poor and confused that it is easy to demonstrate that the innate learning program prevails over the environmental stimuli, Bernstein emphasizes the predominant role played by the environment in shaping the learning process. Of course, the correlation between social class is not, strictly speaking, without exceptions, because much of the learning process depends on the lifestyle of the family under consideration. There are exceptional working-class families where parents, contrary to all expectations, have good knowledge of the language and place great importance on culture, but the norm is that, within working-class families, cultural stimuli are less predominant than in more well-off families.

The problem, for sociologists, is how to offset the disadvantages of the pupils belonging to working-class families and how pedagogues (and teachers) can have an antideterministic effect on such children.

A possible solution to the problem is to ensure that the school (or the class) becomes another miniature family and that the negative effects of the families are compensated for by the pedagogical action of the school. The school should, therefore, be a positive environment in which pupils are exposed to positive cultural and affective stimuli that help their personalities grow and come to maturity. In such a model of the school, teachers lose their primary function of being transmitters of notions (knowledge, in general) and are required to take the roles of educators or pedagogues who act as models and provisionally replace (at least within the boundaries of the school) the family by setting good examples for the students, and, in particular, exposing them to the positive aspects of culture, intended as knowledge that interacts with the

individual to make him or her grow up intellectually and emotionally. To compensate for the negative effects of families, within which dialogue and conversation have died, or are confined to adjacency pairs consisting of questions/answers or orders/replies, teachers have to play the role of communicators and have to stimulate communication. It is, in my view, impossible for a student to make progress in his or her language (to develop a more articulated written or oral mode of expression) unless he or she understands the function of communication, which is that of transmitting knowledge, but also of enhancing the expressive as well as the interpersonal function. To communicate is not only to express propositions (concerning others), but also to express propositions concerning what we really are and feel, and, by so doing, to interact with others, creating an intersubjective dimension in which social life is possible (see Capone, 2003).

Code Switching

S Gross, East Tennessee State University, Johnson City, TN, USA

© 2006 Elsevier Ltd. All rights reserved.

In many bi- and multilingual communities around the world, speakers need to choose, often at an unconscious level, which language to use in their interactions with other members of the community. One of the choices that bilingual speakers often make is to code-switch: that is, speakers switch back and forth between languages (or varieties of the same language), sometimes within the same utterance (*see* **Bilingualism; Code Switching and Mixing**).

The motivations for code switching have often been treated simply as lists of possible functions for code switching. For example, Appel and Muysken (1987) cite five such functions. First, code switching may serve a referential function by compensating for the speaker's lack of knowledge in one language, perhaps on a certain subject. Second, it may serve a directive function by including or excluding the listener. Third, code switching may have an expressive function by identifying the speaker as someone having a mixed cultural identity. Fourth, it may have a phatic function indicating a change in tone in the conversation. And fifth, it may serve a metalinguistic function when code switching is used to comment on the languages involved.

While such lists are useful places to start, and no one would deny that code switching can certainly serve these functions, these types of lists fail to answer the question of what motivates speakers to make the choices they do at a particular point in a conversation. This article reviews the major proposals that have been advanced regarding the following question: why do speakers choose to engage in code switching in the first place?

Code Switching as a Research Topic

The current interest in code switching can be dated to a 1972 study of language use in Hemnesberget, a small village in northern Norway, conducted by Jan Blom and John Gumperz and described in a volume on sociolinguistics edited by Gumperz and Hymes (1972). In Hemnesberget, two varieties of Norwegian are used: Ranamål, a local dialect, and Bokmål, the standard variety (*see* **Language and Dialect: Linguistic Varieties**). However, speakers' decisions regarding which variety to use are by no means arbitrary or haphazard. In general, Ranamål, the local variety, is used in local activities and relationships, reflecting shared identities with the local culture. In contrast, Bokmål is used in official settings such as school, church, and the media, communicating an individual's dissociation from the local group, i.e., not stressing his or her local ties.

Blom and Gumperz distinguish between two main functions of code switching: situational and metaphorical. In situational code switching, which seems to be similar to the notion of diglossia, the speaker's choice of language is constrained by factors external to her/his own motivations, for example, the status of the interlocutor, the setting of the conversation, or the topic of conversation. So, in Hemnesberget, Blom and Gumperz observed that when an outsider joins a group of locals engaged in a conversation, the locals will often switch from the local variety, Ranamål, to the standard variety, Bokmål. In a later work, Gumperz (1982) introduces the distinction between 'we' and 'they' codes, which further

amplifies the kind of linguistic alternation that occurs in situational code switching. 'We' codes are associated with home and family, while 'they' codes are associated with public discourse. In contrast to situational code switching, speakers may engage in a more complex type of code switching to create a 'metaphoric' effect. In his 1982 book, Gumperz explains that this metaphoric effect is a way for speakers to communicate "information about how they intend their words to be understood" (1982: 61). The classic example of metaphorical code switching from the Blom and Gumperz 1972 article is from a conversation at the local community administration office, where two villagers switch from the standard variety of Norwegian, in which they had been discussing official business, to the local variety to discuss family and other private affairs.

The Blom and Gumperz study is important because it illustrates that code switching is a complex, skilled linguistic strategy used by bilinguals to convey important social meanings above and beyond the referential content of an utterance. However, this is not to say that the Blom and Gumperz article has not generated some criticism over the years. In addition to some overlap and lack of clarity in the definitions of situational versus metaphorical switching, this model of code switching implies a sharp boundary between the two types of switching. In fact, Myers-Scotton (1993: 55) argues that the metaphorical meaning of a switched utterance is derived from its situationally based meaning. In any case, it is fair to say that this Blom and Gumperz study sparked an interest in studying code switching data in terms of a dynamic, interactional model that focuses on individual choices rather than static factors related to an individual's social status (*see* **Social Class and Status**).

The Audience-Centered Approach to Code Switching

Using a social psychological theory of language use, Howard Giles and his associates have developed a model of interpersonal communication that considers how speakers change the way they speak according to their audience. Giles refers to this type of strategy as accommodation (*see* **Speech Accommodation Theory and Audience Design**). Within Giles's speech accommodation theory, speakers are motivated by their desire for approval *vis-à-vis* their desire to dissociate themselves from the hearer. These concerns are cognitively salient and are realized by speech convergence (similar styles of speaking) or divergence (different styles of speaking). In fact, Giles predicted from these assumptions that the greater the effort in converging, the more favorably the individual will be evaluated by the listener. Thus, convergence and divergence are linguistic strategies to either decrease or increase social distance between participants in a conversation.

Although the premises behind speech accommodation theory have not been rigorously tested using code switching data in any comprehensive way, it is not difficult to see how the model could be used to explain speakers' motivations for code switching. For example, to test the prediction regarding how listeners will evaluate a speaker based on the speaker's perceived effort at converging, Giles *et al.* (1973) conducted an experiment involving bilingual English Canadian students who were asked to rate their reactions to a set of taped descriptions of a simple harbor scene given by bilingual French Canadian students. Different versions of this description – reflecting different levels of linguistic convergence to monolingual English – were presented to the English Canadian raters. The results of this experiment supported the prediction that the greater the effort in converging, the more favorably the speaker would be perceived. More specifically, the most convergent bilingual French Canadian student was viewed as the most considerate and the most concerned about bridging the cultural gap between French and English Canadians.

Speech accommodation theory has been successfully applied mainly in the contexts of dialect or style switching (*see* **Style and Style Shifting**). However, the theory and its predictions still await further testing on code switching in bilingual settings.

The Conversation Analytic Approach to Code Switching

Both the Gumperz and the Giles models of code switching attend to extralinguistic factors such as topic, setting, and participants as influencing speakers' linguistic choices in conversations. Peter Auer (1984) questioned these assumptions and specifically questioned the way 'situation' was defined. For Auer, situation was a not a static set of contextual features that constrain linguistic choices. Rather, situation was seen as a dynamic phenomenon, emerging from the sequential nature of a conversational interaction. Using the terminology and the techniques of ethnomethodology and conversation analysis, Auer argued that the meaning behind code switching must be interpreted on the basis of the linguistic choices made by the participants themselves in the preceding and following turns in a conversation. In other words, for Auer, social meaning is constituted locally rather than at a societal level (*see* **Conversation Analysis; Ethnomethodology**).

Studies that use the technique of conversation analysis typically assign no independent semantic value to either of the languages involved. Instead, the conversational meaning of code switching results from the mere juxtaposition of the two languages, which generates contextualization cues whereby participants signal various contextual presuppositions. Thus, this language switching has a value of its own, independent of the direction of code alternation.

Some have argued that an approach that focuses on the negotiation of meaning as locally constructed cannot generalize across interactions in order to build explanatory theories. However, Auer (1995) has identified several basic code switching patterns that correspond to identifiable meanings, such as participant-related alternations, which reflect language competence or preference on the part of the speaker, and discourse-related alternations, which signal, for example, topic change (among other functions). Nevertheless, most researchers still recognize that in multilingual communities, each language available in the community indexes specific social and interactional meanings, and listeners tend to attribute consistent interpretations to the particular language choices that speakers make (*see* **Pragmatic Indexing**).

The Marked Model: A Speaker-Centered Approach to Code Switching

One of the more richly developed models designed to explain the sociopragmatic motivations for code switching is Carol Myers-Scotton's markedness model, which developed out of her field research in East Africa. The central premise of the markedness model is that speakers are rational actors who make code selections in such a way as to minimize costs and maximize rewards; that is, speakers are concerned with optimizing the outcomes of an interaction in their own favor (*see* **Markedness**).

This notion of the speaker as a rational actor making certain decisions about code choice, albeit at a largely unconscious level, is also evident in speech accommodation theory as well as in Gumperz's approach to code switching. However, unlike these other models, which consign the primary motivation for code switching to the addressee or to some other factor external to the speaker (e.g., topic or social setting), the markedness model is primarily a speaker-centered approach to communication.

Markedness and Communicative Competence

Within the marked model, all code choices fall along a continuum, as more or less marked or unmarked. With respect to bilingual speech, the unmarked choice simply refers to the linguistic variety that is expected, given the societal norms for that interaction. In contrast, marked choices fall at the other end of this continuum; that is, they are in some sense unusual or unexpected for the particular social interaction.

Furthermore, all speakers possess what Myers-Scotton calls a markedness evaluator, or the capacity to evaluate linguistic choices in terms of markedness, as part of their innate communicative competence (*see* **Communicative Competence**). While the capacity to assign markedness readings to linguistic choices is innate, the markedness continuum is established through exposure to the range of linguistic options used in the community.

Explaining Speakers' Choices

All code choices can ultimately be explained in terms of speakers' motivations to optimize the outcomes of the interaction. Most choices that speakers make affirm the norms that are in place for the particular exchange. These are unmarked choices, and they are usually the safest choices to make. The particular code used by the speaker is important only insofar as the participants view its status as marked or unmarked for that type of interaction. Thus, in a multilingual setting such as Nairobi, Kenya, the unmarked choice for most business transactions between strangers is Swahili. However, if the participants discover during the course of their conversation that they are members of the Luyia ethnic group, they will often switch into Luyia to continue the conversation. Luyia, then, becomes the unmarked choice, given the ethnic identity of the participants. However, code switching between Swahili and English within the same turn, within the same sentence, and even within words is typically the unmarked choice for informal social gatherings between educated, middle-class peers in Nairobi. Hence, the markedness of linguistic choices must be evaluated in terms of the norms for a particular exchange; the unmarked setting may even change within a conversation.

In contrast to the relative safety of unmarked choices, marked choices carry with them some element of risk for someone who wishes to defy the norms. Importantly, the interpretation that a marked choice receives derives from its contrast with the unmarked choice for that exchange. That is, the unexpectedness, the 'otherness' of a marked choice carries significant social meaning. Marked choices are typically used to redefine the relationship between the speaker and the addressee, often as an expression of the speaker's authority or power, to indicate anger, or to assert one's ethnic identity (*see* **Identity and Language; Power and Pragmatics**). All these

strategies can be subsumed under a single general principle: speakers make marked choices to negotiate a change in the expected social distance between the participants, either increasing or decreasing it.

The Significance of the Markedness Model

Since its formulation, the markedness model has been successfully used to explain code switching between languages, between dialects and registers, and even between stylistic choices in literary contexts. The strength of the markedness model is its ability to explain not only unmarked choices, which other models do as well, but also its ability to explain marked choices. Furthermore, the markedness model addresses the universal aspects of communicative competence in terms of the cognitive abilities that use readings of markedness to assess speakers' intentions. For these reasons, the markedness model is a powerful tool not only for code switching research, but also for any examination of the ways in which speakers use language to achieve interactional goals.

Code Switching and Mixing

S Mahootian, Northeastern Illinois University, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Code switching is a linguistic phenomenon commonly occurring in bi- and multilingual speech communities. The term, which also appears as 'codeswitching' and 'code-switching' in the literature, broadly refers to the systematic use of two or more languages or varieties of the same language during oral or written discourse. One of the earliest definitions of code switching was provided by Weinreich's (1953) description of bilingualism as "the practice of alternately using two languages." Gumperz (1982: 59) highlights the structural aspects of code switching that have dominated the last three decades of research in this area, by defining code switching "as the juxtaposition within the same speech exchange of passages of speech belonging to two different grammatical systems or subsystems."

Although the conversation patterns observed between bilinguals of the same language backgrounds indicate a predominantly unconscious switching back

strategies can be subsumed under a single general principle: speakers make marked choices to negotiate a change in the expected social distance between the participants, either increasing or decreasing it.

The Significance of the Markedness Model

Since its formulation, the markedness model has been successfully used to explain code switching between languages, between dialects and registers, and even between stylistic choices in literary contexts. The strength of the markedness model is its ability to explain not only unmarked choices, which other models do as well, but also its ability to explain marked choices. Furthermore, the markedness model addresses the universal aspects of communicative competence in terms of the cognitive abilities that use readings of markedness to assess speakers' intentions. For these reasons, the markedness model is a powerful tool not only for code switching research, but also for any examination of the ways in which speakers use language to achieve interactional goals.

Code Switching and Mixing

S Mahootian, Northeastern Illinois University, Chicago, IL, USA

Code switching is a linguistic phenomenon commonly occurring in bi- and multilingual speech communities. The term, which also appears as 'codeswitching' and 'code-switching' in the literature, broadly refers to the systematic use of two or more languages or varieties of the same language during oral or written discourse. One of the earliest definitions of code switching was provided by Weinreich's (1953) description of bilingualism as "the practice of alternately using two languages." Gumperz (1982: 59) highlights the structural aspects of code switching that have dominated the last three decades of research in this area, by defining code switching "as the juxtaposition within the same speech exchange of passages of speech belonging to two different grammatical systems or subsystems."

Although the conversation patterns observed between bilinguals of the same language backgrounds indicate a predominantly unconscious switching back

and forth between the two languages, this is not to say that switching occurs randomly. In fact, over the last three decades, researchers in the area of language contact have come to a consensus that code switching is a systematic rule-governed linguistic behavior.

Switching may be conscious and intentional. Intentional switching may be used to indicate shifts in topic, change in interlocutor, and change in interpersonal or social relationships. Much of the time, however, switching between languages is unintentional. It is the result of psycho- and sociolinguistic variables that the speaker is not consciously aware of, involving processing issues and the tendency of speakers to adapt their speech style to the interlocutor's style and/or community norms and expectations.

Although switching has at times been associated with language attrition, indicative of weakness in one of the bilingual's languages, many researchers believe that code switching is in fact a natural consequence of competence in more than one language and that it should not be mistaken for a language deficit.

The following are some examples of code switching between (1) Farsi-English, (2) Irish-English, (3) Japanese-English, and (4) Arabic-French.

(1) gofte bud ke she wanted to get revenge.
said was that _____
'She had said that she wanted to get revenge.' (Mahootian, 1993)

(2) Ta carr light green aige
be car _____ at him
'He has a light green car.' (Stenson, 1990)

(3) one algebra question o mark shite
_____*ACC.* ____ *do*
'you mark one algebra question' (Nishimura, 1991)

(4) un professeur ʔaDim
a professor excellent
'an excellent professor' (Bentahila and Davies, 1983)

Types of Code Switching

Two main types of code switching can be identified. Switching between languages at sentence or clause boundaries is called intersentential. Switches within a clause involving a phrase, a single word or across morpheme boundaries are intrasentential switches. Some researchers identify tag switching as a third type of switching, separate from intersentential switching. Tag switches involve the insertion of tag forms such as *I mean, you know, isn't it?*, etc., from one language into an utterance of another language. Example (5) shows an instance of intersentential switching between Puerto Rican Spanish and English; (6) and (7) are examples of intrasentential switching, and (8) is an example of a tag switch between Farsi and English.

(5) Sometimes I'll start a sentence in English
y termino en español
_____ *and finish it in Spanish*
'Sometimes I'll start a sentence in English and finish it in Spanish.' (Poplack, 1980)

(6) I'm shuxi-ing with you.
___ joke-_____
'I'm joking with you.' (Mahootian, 1993)

(7) Your bag is zir-e miz
_____ under of table
'Your bag is under the table.'

(8) It was a good performance, nae?
_____, no?
'It was a good performance, wasn't it?'

Code Mixing

Some researchers have used the term 'code mixing' (also 'codemixing' and 'code-mixing') to refer specifically to intrasentential switching, and code switching to refer to intersentential switching. In most current literature, however, the term 'code mixing' is used interchangeably with 'code switching,' with both terms referring to both types of language mixing. Recently, a few researchers have made finer distinctions between the two terms, using 'code mixing' and 'mixed code' to distinguish the use of two or more languages at the discourse level from switches within clauses/words.

In studies of child bilingualism, however, 'code mixing' carries additional implications. Depending on the researcher's view *vis-à-vis* children's ability to keep their two languages separate, code mixing can be seen as either a sign of the child's display of two differentiated code systems or an underlying unified system. Mixing in the former case refers to the same phenomenon found in adult mixed speech. In the latter, mixing refers to the use of the 'wrong' language in a monolingual context. More on this topic can be found in 'Bilingual Language Acquisition and Code Switching.'

Borrowings, Nonce Borrowings, and Loanwords

Adequately defining bilingualism and distinguishing between two of its related features, code switching and borrowing, has been an ongoing challenge for researchers. Borrowing is not a new phenomenon and can be seen as part of the development and lexical expansion of all languages. The most significant reason that languages borrow from one another is also the most obvious. Borrowing is motivated primarily

by cultural contact, whether through trade or war. Along with new ways, styles, foods, religions, forms of government, etc., new words for these items are introduced into the community. For example, looking at the history of the development of the English language we see the influence of Latin and French in everyday words such as *plant, pear, organ, bishop, heretic, pot, cook,* from Latin, and *cardinal*, *duke*, *court*, *abbey, beef, mutton, joy, poor, fruit,* from French.

Traditionally, the term 'borrowing' has been used to refer to any word or phrase taken from one language and used by the **monolingual** speakers of another language. Usually, borrowings fill lexical gaps arising from imported concepts, such as *telephone, television, fax, pizza*, etc. Before a word or phrase becomes a fully legitimate borrowing and becomes fully integrated into the host language, it goes through a few stages. Usually the target word is introduced into a language through bilinguals. At this stage, the word is not phonologically or morphologically integrated into the host language and its usage is more or less limited to bilinguals. Once a foreign word becomes part of the monolingual speech of a host language, most researchers agree that it has become part of the host language and hence a language borrowing. At this stage, the borrowed word will also show signs of adaptation to the morphology and phonology of the host language.

However, since borrowing is typically a gradual process, there are a number of factors that have been identified as relevant to distinguishing code switches from borrowings. First among these is the length of a borrowed utterance and the degree of morphological and phonological integration of the utterance into the host language. Opinions on the degree of integration range from fully integrated single words that have been completely adapted to the host language phonology and morphology systems, such as the Japanese word *takshi* [takʷši] borrowed from the English *taxi* [tæksi], to phrases of any length showing partial integration (Reyes, 1974; Pfaff, 1979; Haugen, 1956; Hasselmo, 1970; Grosjean, 1982; Mahootian, 1993). Frequency of occurrence in the host language has also been identified as a factor, with the idea that borrowings occur more frequently than code switches (Poplack *et al.*, 1988; Myers-Scotton, 1993).

Loanwords

Based on degree of integration, borrowings are further classified as either loanwords or nonce borrowings. Words fully integrated and used by monolinguals, usually without any knowledge of the words' origins, are loanwords. Loanwords can be further categorized as necessary loans and unnecessary loans. Necessary loans fill lexical gaps or accompany specific items brought into the host culture. Some examples of necessary loanwords in English are *pajamas*, *whiskey*, *chili*, *croissant*, *robot*, *orange*, and a host of other words that most monolingual English speakers probably do not recognize as borrowings. Food, fashion, technology, etc. are typical candidates for necessary loans. Unnecessary loans, as their label implies, do not fill in gaps. In fact, they coexist with the native analog but usually in a semantically altered fashion. For example, the French word *veal*, meaning 'yearling' or 'calf', did not simply replace the English word 'calf,' which also referred to the young animal and, therefore, blocked the French word from applying to that meaning. *Veal* could, however, be used for some other related meaning and was used to refer to the meat from the animal rather than the animal itself.

One of the reasons often cited for the unnecessary loans is that the guest language is associated with prestige by speakers of the host language, but there are many cases where prestige cannot account for such borrowings. A case in point is English borrowings in Japanese. For example, the word *maketo* (<market) connotes a modern image of an indoor market. Its Japanese equivalent, *ichi*, on the other hand, refers to an outdoor market, located under a tent. Clearly, *maketo* is borrowed into Japanese not for prestige but rather to make a useful distinction. Another example is the word *senta* (<center, as in an institution). The Japanese morpheme *-sho*, meaning 'center' conveys a less equipped place. The borrowed word *senta*, on the other hand, conveys a well-equipped, better-made, larger space, with modern furniture. The suffix *-sho* is also used for places that do not cater to fun/positive activities, such as *keimusho* 'jail.' Other such borrowings are used euphemistically. For example, the words *babysitter, nationalism*, and *bargain* are used in Japanese when a speaker wants to elevate or downplay the negative connotations of the Japanese equivalents. Romaine (1995) makes similar observation about English borrowings in Punjabi.

Distinguishing Borrowings from Code Switches

As mentioned earlier, one of the major problems confronting researchers in the area of language contact is how to distinguish between code switching and borrowing. These two have generally been considered different phenomena that produce mixed sentences. Most researchers agree that switching can be of any length. It can occur at the word, phrase, or sentence

level as long as it is a complete shift into the other language, as in example (9) below:

(9) Ça m'étonnerait qu'on ait code-switched autant que ça.
'I can't believe that we code-switched as often as that.' (Grosjean, 1982).

In this example the word 'code-switched' has been code switched, because the speaker has used an English term with an English pronunciation and past participle form in an otherwise French sentence.

In contrast, borrowings tend to be short and phonologically and morphologically adapted to the host language. For example, the word 'code-switché' in sentence (10) is an instance of borrowing (Grosjean, 1982). The English term 'code switch' is pronounced and inflected in French.

(10) Ça m'étonnerait qu'on ait CODE-SWITCHÉ autant que ça.
'I can't believe that we code-switched as often as that.'

The distinction between code switching and borrowing is important in sociolinguistics, where the decision to code switch or not is an integral part of the dynamics of a community (see 'Functions of Code Switching'). Until the early 1990s, linguists interested in the structure of code switching had also honored the distinction between switching and borrowing, with the implication that borrowings behave differently syntactically. However, for the distinction to be useful, it would have to rest on three interrelated assumptions:

1. borrowing and code switching are two conceptually distinct linguistic phenomena,
2. we can systematically and consistently separate the two phenomena, and
3. the distinction will hold across languages in a way that allows us to make generalizations about each phenomenon.

The criteria set thus far for distinguishing the two are not infallible. Since code switching can occur on a single-word level as well in longer utterances, length of utterance does not offer a clear-cut distinction. Phonological adaptation also fails to be foolproof. For example, if a bilingual speaker has transferred the phonological system of L1 to L2 while acquiring L2 (in other words the speaker has an accent), it will be difficult to evaluate whether word X from L2 has been borrowed into an L1 sentence or if the speaker has code switched into L2. Most researchers acknowledge the shortcoming of using morphological adaptation as a guideline in cases where the switch may be only one word such as an adverb or an uninflected free morpheme. Some researchers claim to have developed operational criteria for distinguishing borrowings from code switches. Their operational criteria rest on establishing a parallel between nonce borrowings and established loanwords. They assert that nonce borrowings, like established loans, are morphologically and syntactically integrated into the host language but code switches are not.

Nonce Borrowings

Despite some evidence that nonces are loanwords, there is more evidence that they are not. First, nonce borrowings, like code switches, are only used by bilinguals, not monolinguals.

Second, loanwords are established, recognized by the community as part of the native lexicon, and used as frequently and naturally as other native lexical items. Nonce borrowings are spontaneous usages, not established, with no guarantee of recurrence – just as code switches are spontaneous, not established, with no guarantee of recurrence.

Third, loanwords are phonologically adapted to the host language but nonce borrowings are not. Here too, nonce borrowings behave like code switches.

Fourth, morphological adaptation, as mentioned earlier, is not a foolproof criterion. It may be true that all words morphologically adapted into the host language are borrowings. However, what about words that have no overt morphology? Are they automatically code switches by default?

Fifth, syntactic adaptation also has its limits. For example in the case of two languages with the same word order, such as Spanish and English, would the word *slowly* in sentence (11) be considered a code switch or a borrowing? In cases such as (11), syntactic adaptation fails to be a clear criterion.

(11) Lo hizo slowly.
'He did it slowly.' (Woolford, 1983)

According to proponents of the nonce borrowing hypothesis, *slowly* could be either a nonce borrowing or a code switch.

Matrix and Embedded Languages

The distinction between matrix or host language and embedded or guest language is a crucial part of a number of code switching accounts. However, no feasible criteria have been established that systematically distinguish the matrix language from the embedded language in all instances of code switching. Some have proposed the base language should be whichever language the syntax of the utterance belongs to or whichever language provides the inflectional and

derivational morphemes. Myers-Scotton distinguishes between system morphemes, or grammatical morphemes, and content morphemes, the morphemes that assign thematic roles. System morphemes come from the matrix language. Joshi uses speaker intuition as the basis for distinguishing matrix from embedded language. He claims that in mixed discourse, speaker and hearer 'usually agree' on which language is the matrix language. However, as the following example indicates, not all bilingual speakers seem to be conscious of their switches, let alone which language frame they are using.

(12) I mean I'm guilty in that sense ke ziada wsi English i bolde fer ode nal eda . . . wsi mix kerde rene ã. I mean, unconsciously, subconsciously, keri jane e . . .
'I mean I'm guilty in that sense that we speak English more and more . . . we keep mixing. I mean unconsciously, subconsciously, we keep doing it. . .' (Romaine, 1995)

Not all researchers agree with these criteria. For example, Romaine (1995) notes that the syntax and morphology criteria would not work for Punjabi-English. Nor, as she and others have pointed out, would they yield unequivocal results in all instances. The mixed utterances in (13)–(15) underscore the problematic nature of the criteria proposed for the matrix/embedded distinction. In (13), for example, Japanese structure overlaps with English structure; therefore, it will not be possible to assign matrix language based on syntax. In cases such as (14) and (15), where a single system morpheme is in one language and the remaining utterance is in the other language, it seems counterintuitive, or at least problematic, to designate the language of the grammatical morpheme as the matrix.

(13) Dakedo I don't like New York
but _____
'But I don't like New York.' (Jap-Eng; Nishimura, 1985)

(14) E baguette, s'il vous plaît . . .
a baguette please
'A baguette please . . .' (Alsatian-Fr; Gardner-Chloros, 1991)

(15) Lawyer-et will tell you what to do.
_____-2P-POSS _____
'Your lawyer will tell you what to do.' (Farsi-Eng; Mahootian, 1993)

In addition to the unreliability of the proposed criteria for distinguishing matrix language from embedded, some researchers have pointed out that syntactic analyses of code switching, by virtue of their claim to be based on principles of universal grammar, should not need to resort to such a distinction.

Social and Pragmatic Functions of Code Switching

Early studies of code switching were embedded in studies of language contact and bilingualism. The most significant of these studies were carried out by Weinreich (1953), Haugen (1953), Hasselmo (1961), and Clyne (1972). By the early 1970s, code choice and code mixing were taking more of the spotlight as researchers became interested in the conversational functions and the social motivations of the byproducts of bilingualism. A number of functions were identified and associated with code switching, with most, if not all, directly or indirectly related to a complex of interconnected social and contextual variables or domains such as situation, interlocutor, and topic of discourse. Bilinguals' code switching was likened to monolinguals' style shifting. It was argued that having more than one language gave bilingual speakers a choice of an additional discourse mode. Giles *et al.* (1977) proposed that in addition to these domains, code switching and language choice are also influenced by sociopsychological forces. This approach, known as accommodation theory, would, for example, predict that speakers' needs or desires to associate with or disassociate from a group will direct their language choice.

Referential and Expressive Switching

The two functions most discussed in the literature until the early 1980s were the referential and the expressive functions of code switching. The referential function of code switching refers to the types of code switches that are primarily motivated by lexical gaps, or lack of fluency about a topic in one language, or simple failure of lexical retrieval. This function of code switching highlights the fact that the notion of balanced bilingualism is more an issue of theoretical competence rather than a reality. It is often the case that a bilingual can discuss some subjects more easily in one language than the other. For example, individuals whose home language (L1) differs from the language in which they have been educated (L2) are more at ease discussing academic concepts in the L2 and will therefore switch to the L2 to do so. This is true with regard to technical or culture-specific concepts as well. Tuning in to non-English radio stations in the United States reveals an interesting pattern of code switching. The native-language broadcasts are peppered with English terms for traffic flow, weather conditions, and local events.

The expressive function of code switching is associated with a meta-level act of communication where the form itself, meaning mixed speech discourse, is a comment about the speaker rather than the speech.

The relationship between language and identity has long been established and documented. Language is both co-constructor and a reflection of social identity. This relationship becomes more complex in bilingual communities where the languages and cultural/ethnic values and identities bear unequal social prestige. Studies of Spanish-English code switching among Puerto Ricans in New York and of code switching in the media conclude that speakers choose mixed code as a way to emphasize their bilingual/bicultural identity.

Metaphorical and Transactional Switching

The concepts of metaphorical or nonsituational and transactional or situational code switchings were introduced to capture two functions of code switching (Blom and Gumperz, 1972). Transactional switching is motivated by variables such as topic and interlocutors. Metaphorical switching, on the other hand, accounts for the extralinguistic message the speaker wishes to express, the effect the speaker wants to have on the hearer. Metaphorical code switching is viewed as an indication of the speaker's momentary attitudes and emotions with social variables (class, situation, speakers, topic, etc.) and ideological variables (identity, group affiliation, etc.) as important contributors to the form of the message (Gumperz, 1982). In his seminal work on discourse strategies, Gumperz characterizes bilingual speakers and bilingual speech communities as "marked both by diversity of norms and attitudes and by diversity of communicative conventions" (Gumperz, 1982: 71). In an attempt to capture uniformity across different bilingual language exchanges, he posits five conversational functions of code switching: (Gumperz, 1982: 77ff):

1. Quotation: to distinguish between direct speech and quotations or reported speech: When quoting or reporting someone else's discourse, speakers will often switch into that person's language, as in the following Farsi-English example:

   unvaeqt jan be maen mige, "I don't think I can make it."
   then John to me says _____
   'Then John says to me, "I don't think I can make it."'

2. Addressee specification: speakers may code switch in order to "direct a message to one of several addressees" (Gumperz, 1982: 77):

   'Well I don't know how to describe it but it just doesn't feel like home to me (directed to Hearers 1 and 2; H1 is monolingual, H2 bilingual), to miduni maenzuraem chie, doroste? (you know what I mean, right?' directed to H2). (Farsi-Eng)

3. Interjections: speakers may code switch as a way to mark an interjection as in the phrase 'you know' in the Panjabi-English sentence below:

   I wish, <u>you know</u> ke m3 pure Panjabi bol s3ka
   'I wish, you know, that I could speak pure Panjabi' (Romaine, 1995: 122)

4. Reiteration: speakers may switch languages to emphasize or clarify a message:

   Ven acá, ven acá, <u>come here, you</u>.
   Come here, _____. (Sp-Eng;
   come here, Gumperz, 1982: 78)

5. Message qualification: speakers may switch to add more information in order to qualify the main message.
6. Personalization versus objectification: in this category, switching marks a number of related functions that reflect the degree of speaker involvement or distancing *vis-à-vis* the message, the interlocutors, etc.

Related to the sixth category, Grosjean (1982: 152) identifies a number of additional discourse functions such as marking group identity, emphasizing solidarity, excluding others from a conversation, raising the status of the speaker, and adding authority or expertise to a message.

Though not comprehensive and by his own admission limited, Gumperz's view of the sociopragmatic functions of code switching captured the dynamic nature of language choice and was an important first step to a fresh look at an old phenomenon. Many of the same ideas and observations concerning the discourse functions of code switching were recast by Auer (1984) in a conversational analysis framework and by Appel and Muysken (1987) in the functional framework of Jakobson (1960) and Halliday *et al.* (1964). Based on her work in Africa, Myers-Scotton also suggested that code switching "serves the same general socio-psychological functions everywhere" (Myers-Scotton, 1988: 3) and proposed the markedness model of code switching to "explain the socio-psychological motivations behind CS [code switching]" (Myers-Scotton, 1988: 3).

Attitudes Toward Code Switching

Despite the pragmatic functions that code switching/language mixing serves and clear evidence that code mixed utterances are structurally rule-governed and systematic, in most communities, code switching usually has a stigmatized status. This is not to say that all bilinguals or all bilingual communities consider code switching to be negative. In fact, in all bilingual

communities one finds that attitudes toward mixed language range from positive to negative, depending on class, age, education, profession, and other social factors. For example, older generations of speakers in a bilingual community typically have a negative response to code switching and assert that it shows a loss of pride in the home culture and disrespect to the community elders, not to mention ignorance and laziness. They avoid code switching and usually expect the languages to be kept separate and hence 'pure.' Younger generations are expected to do the same, at least in the presence of their elders. This ideal of language purity is a strong social constraint on language mixing and can be found across many bilingual communities.

Who holds what attitude is not necessarily predictable, however, and can vary from community to community and from language pair to language pair. In part, attitude is tied to a group's position on bilingualism, to the social status of each language, as well as to the status of the immigrant group in the host country. For example, Puerto Ricans in New York have a positive attitude toward bilingualism and code switching. For them, code switching is frequent and occurs in both directions, i.e., from Spanish into English and from English into Spanish. Mixing two languages is an important way to show the speakers' affiliation and connection to both their cultures. In the same vein, in some social contexts, using mixed language discourse is considered the unmarked or expected form, and not mixing is considered marked or unexpected.

Conversely, until recently, among Mexican-Americans, code switching was highly stigmatized and referred to pejoratively. It has been noted that when political ideology changes and a group becomes more conscious of their ethnicity, attitudes toward code mixing change. For example, Romaine (1995) points to the reversal of the previously pejorative use of *pocho* and *caló* used in California and the southwestern United States to refer to the variety of Spanish-English spoken by Chicanos. She ties this shift to a heightened ethnic awareness among Chicanos.

Structural Accounts of Code Switching

Studies of the structure of code switching fall into four categories: descriptive accounts (Timm, 1975; Pfaff, 1979); accounts involving surface constraints and a third grammar for code switching (Poplack, 1980; Sankoff and Poplack, 1981); principle-based accounts involving special mechanisms (Belazi *et al.*, 1994; Bentahila and Davies, 1983; Di Sciullo *et al.*, 1986; Joshi, 1985; Woolford, 1983); and principle-based accounts without code switching-specific mechanisms or constraints (Mahootian, 1993, 1996a, 1996b; Myers-Scotton, 1993).

Overall, these approaches show the progression of code switching accounts moving from a view of code switching as only a dynamic social phenomenon to code switching as a language phenomenon that can inform linguistic theory at other levels such as syntax, morphology, and language acquisition.

Descriptive Accounts of Code Switching

Until the early 1970s, linguists generally considered the grammatical implications in one of two ways. On the one hand, grammatical implications were ignored because it was assumed that the internal structures of sentences have no bearing on the motivations for switching. On the other hand, some researchers concluded that the failure to find rules or constraints indicated that codes witching was syntactically unrestricted and irregular.

However, in the course of the 1970s, some linguists suggested that code switching does not occur syntactically randomly. A number of descriptive accounts, mostly about Spanish and English, observed that switching between languages seemed to follow certain patterns. For example, based on their data of Spanish-English code switches, Timm (1975) and Gumperz (1976) noted that switching did not occur between the subject pronoun and the finite verb. They proposed that switching was in fact prohibited between those elements, shown in examples (16) and (17) from Timm (1975: 477).

(16)	Pron	Subj	Verb		
	Sp	Eng	*Yo went;	*El wants;	*Ellos gave.
	Eng	Sp	*I fui;	*He quiere;	*They daban

(17)	Verb	Pro	Obj	
	Sp	Eng	*Mira him;	*Him mira
	Eng	Sp	*She sees lo	*Lo she sees

Pfaff (1979) described further constraints on Spanish-English code switching. She noted in the case of switches between adjective and noun that the resulting mix must not violate the surface word order of either language. Hence switches between English nouns and postnominal Spanish adjectives are prohibited, as shown in example (18). However, switching between determiners and their NPs, shown in example (19), is allowed.

(18) *<u>I went to the house</u> chiquita
<u>_____</u> small
'I went to the small house.' (Pfaff, 1979)

(19) el <u>same day</u>
the <u>_____</u>
'the same day' (Pfaff, 1979)

A Three-Grammar Approach

Results such as those obtained by Timm and Pfaff led researchers to look for ways to formulate the apparent constraints on code switching. The first effort at formalizing constraints was made by Sankoff and Poplack (1981). They suggested that bilinguals have a code switching grammar separate from the grammar of their two languages. That is, they claim bilinguals have a third, code switching grammar along with their two monolingual grammars. Their code switching grammar comprises the lexicon of the two languages plus the grammatical categories of the two languages.

Poplack (1980) and Sankoff and Poplack (1981) also proposed two universal constraints on code switching. The Free Morpheme Constraint prohibits a switch between a stem and an affix unless the affix has been phonologically integrated into the language of the stem. Accordingly, mixed utterances such as in example (20) are disallowed.

(20) *eat-iendo
'eating' (Poplack, 1980)

Their second principle, the Equivalence Constraint, operates on surface structures. Its simplest form states that the word order before and after a switch must be possible in both languages. In the example below, (21c) is the speaker's utterance, (21a) and (21b) are the corresponding English and Spanish forms, and therefore the switch in (21c) is possible (Poplack, 1980: 586):

(21a) Eng: I told him that so that he would bring it fast
(21b) Sp: (Yo) lo dije eso pa' que (el) la trajero ligero
I him told that so that he it bring fast
(21c) CS: I told him that PA' QUE LA TRAJERO LIGERO

However, the switch between the noun and adjective in example (22) is ruled out since the noun-adjective order is exclusive to Spanish:

(22) *the casa big
___ house ___
'the big house' (Woolford, 1983)

Despite their seminal work showing that code switching is syntactically systematic and rule-governed, Sankoff and Poplack's model has been criticized for falling short on two levels. On the conceptual level, since every language requires a third code mixed grammar, a trilingual speaker would be carrying around seven grammars. This number jumps to 15 for the quadrilingual. Such an increase in the number of grammars seems unlikely.

Second, both of their proposed constraints have been shown to be too strong. The equivalence constraint that operates on linear order disregards the hierarchical relationship among categories and constituents. Consequently, although the constraint adequately predicts switches between Spanish and English, it fails to predict possible switches in the case of typologically dissimilar languages, such as English (SVO) and Japanese (SOV). In example (23), an English adverb is used in Hindi word order and precedes the verb. Example (24) shows a Farsi object DP (determiner phrase) following the verb. In example (25), an English adjective follows an Irish noun and in example (26) a Japanese postposition follows an English DP.

(23) pušpa bahut quickly bat karh hai
Pushpa very _____ word do-PROG
'Pushpa talks very quickly.' (Hindi-Eng; Di Sciullo *et al.*, 1986)

(24) I love xormalu
_____ persimmon.
'I love persimmon.' (Farsi-Eng; Mahootian, 1996a)

(25) Ta carr light green aige
be car _____ at him
'He has a light green car.' (Ir-Eng; Stenson, 1990)

(26) I slept with her basement de.
_____ in
'I slept with her in the basement.' (Jap-Eng; Nishimura, 1985)

Second, the Free Morpheme Constraint proposed as a general constraint on code switching predicts no switching between a bound morpheme of one language and a phonologically unassimilated lexical item of another language. This prediction is not borne out, as seen in the following examples from Arabic-English (Prince and Pintzuk, 1984: 2), Irish-English (Stenson, 1990: 180), and Japanese-English (Nishimura, 1991: 31).

(27) inta hang-ha up
you ____ -it ____
'you hang it up'

(28) job-anna
____-PL
'jobs'

(29) one algebra question-o mark-shite
_____ACC _____-do
'(you) mark one algebra question, and . . .'

The Sankoff and Poplack model accounts for examples such as (23)–(28) by designating the switches as borrowings.

Principle-Based Approaches with Special Mechanisms

The limitations of Sankoff and Poplack's surface level constraints led other researchers to look for more principle-based constraints to account for code switching. Code switching was seen as an additional process that needed to be accounted for by special rules/constraints outside the bilingual speaker's two monolingual grammars but motivated by universal principles of grammar. Toward this end, a number of code switching models were proposed: Woolford's phrase structure congruence model (1983), Bentahila and Davies' subcategorization restrictions model (1983). Joshi's closed-class item constraint (1985), Di Sciullo *et al.*'s government constraint (1986), and Belazi *et al.*'s Functional Head Constraint (1994).

Phrase Structure Congruence Model Woolford (1983) argues for an account of code switching that follows from "the manner which monolingual grammars cooperate to produce hybrid sentences" (Woolford, 1983: 519). Woolford argues against an autonomous code switching grammar, citing as evidence the fact that we do not find utterances such as (30b) where English lexical items in a Spanish structure produce an unacceptable utterance (Woolford, 1983: 521):

(30a) No estoy terca. (Spanish)
not am stubborn
'I'm not stubborn.'

(30b) *Not am stubborn.

In this model, the lexicon and word formation rules of the two languages are assumed to be separate and cannot interact. Instead she proposes that the monolingual grammars interact at D-structure at the level of phrase structure rules, where "the two grammars operate during code-switching just as they do during monolingual speech" (Woolford, 1983: 522). Therefore, while dropping the subject pronoun is acceptable in Spanish (30a), pro-drop is not permitted in English (30b). Woolford's model, like her predecessors', also prohibits morphologically mixed French-English lexical items such as **savoir-ing*.

Terminal nodes of phrase structures can only be filled from the lexicon of the grammar that generated them. Code switches result when a phrase structure is identical in both languages and "both lexicons have equal access to terminal nodes created by common rules" (Woolford, 1983: 524). For example, in both Spanish and English the determiner precedes the noun. Therefore, we should expect to get the four following combinations the phrase 'the old man'.

(31) the old man

(32) el hombre viejo
the man old
'the old man'

(33) the hombre viejo

(34) el old man

On the other hand, the rule that adjectives follow nouns is unique to Spanish. Woolford's model predicts we will get the utterance in (35) but not the ones in (36)–(39):

(35) el hombre viejo
'the old man'

(36) *el man viejo
'the old man'

(37) *el hombre old

(38) *the old hombre

(39) *the man old

Although accepted and incorporated into others' models of code switching, the noun-adjective prediction was shown to be wrong by Mahootian and Santorini (1994) and Santorini and Mahootian (1995). Their account of switching between nouns and adjectives uses the distinction between complements and adjuncts on the one hand and attributive and predicative adjectives on the other, to account for and predict noun-adjective switches between languages with dissimilar NP structures such as Spanish and English, Italian and English, and Irish and English:

(40) I want a motorcycle verde
_____ green
'I want a green motorcycle.' (Sp-Eng; McClure, 1981: 87)

(41) Ma ci stanno dei smart italiani.
'But there are smart Italians.' (It-Eng, Di Sciullo *et al.*, 1986: 15)

(42) do gheansai deas pink
your sweater nice ____
'your nice pink sweater' (Ir-Eng; Stenson, 1990: 171)

The main criticism brought against Woolford's model is its inability to account for switches involving structurally dissimilar languages. With the exception of noun-adjective switches, Woolford's approach successfully accounts for Spanish-English, but like Sankoff and Poplack's equivalence constraint, its reliance on the order of constituents in a phrase renders it too strong when dealing with languages whose word orders differ such as Hindi-English, Farsi-English, Arabic-French, Irish-English, etc.

Although Woolford's model does not account for the full range of code-switching data, it captures

two significant generalizations about the process of code switching. First, code switching is an ordinary language-use phenomenon that is part of our grammar system and does not require a third grammar, and second, switches involve cross-linguistically corresponding categories. These two insights figure prominently in models that followed a decade later.

Subcategorization Restrictions Intrasentential code switches between Moroccan Arabic and French led Bentahila and Davies (1983) to conclude that there are no surface constraints on switching and that, for at least Arabic-French, switching is constrained **only** by language-specific subcategorization restrictions. Accordingly, they were able to account for switches within VP even where the structure of the two languages are dissimilar, as is the case of Moroccan Arabic (VSO) and French (SVO). Although they do not explicitly define it as such, in application their notion of subcategorization restrictions is equal to sisterhood. Accordingly, they allow for the switch in (43), where an Arabic adjective (which subcategorizes as postnominal) follows a French noun (Bentahila and Davies, 1983: 321):

(43) un professeur ʔaDim
a professor excellent
'an excellent professor'

However, they wrongly block switches like the one in example (44), where an Arabic adjective precedes a French noun, thus violating the subcategorization rule for Arabic adjectives. As mentioned earlier, these types of switches were later addressed and accounted for by Mahootian and Santorini.

(44) un ʔaDim professeur
a excellent professor
'an excellent professor'

The subcategorization model also prohibits switching at word-internal morpheme boundaries for which they postulate a constraint similar to Sankoff and Poplack's Free Morpheme Constraint.

Bentahila and Davies' model of switching has an advantage over other models. Although they cannot account for word-internal switches or the range of possible noun-adjective switches, their model accounts for a wide range of intrasentential switches by simply invoking the universal principle of subcategorization restrictions.

The Closed-Class Item Constraint Joshi (1985) also proposed a system for code switching where the grammars of the two languages are kept separate. There is no merging of the phrase structure rules or lexicon of the two languages. Rather the proposed switching constraints are grounded in basic principles of language and grammar.

The system he presents involves a matrix language L_m with a corresponding grammar G_m and an embedded language L_e with grammar G_e. He assumes a correspondence between grammatical categories across the two grammars so that the structure of a DP in one corresponds to the structure of DP in the other.

Joshi places three constraints on switching. The first is asymmetry, which specifies that switching can only occur in one direction: from matrix language to embedded language. The second constraint prohibits switches from occurring at the root node of the matrix language (S_m). The third constraint, the Closed-Class Item Constraint, prohibits switching of closed-class items including determiners, quantifiers, prepositions, possessive, Aux, Tense, etc., meaning that all closed-class items must be in the matrix language.

Two related problems have been noted with this model. In the first place, the viability of the asymmetry constraint is questioned. Asymmetry depends on the distinction between matrix language and embedded language. Joshi claims "speakers and hearers usually agree on which language the mixed sentence is 'coming from'" (Joshi, 1985: 193). However, as noted earlier, this criterion, along with others proposed to distinguish matrix language from embedded language, is unreliable. Consequently, since matrix and embedded languages are not systematically discernible from each other, the closed-class item constraint loses its viability. The following are some examples of switches that violate the predictions of the Closed-Class Item Constraint.

(45) Anyway, I figured ke if I worked hard enough,
_____ that_____
I would be finished by summer.
'I figured that if I worked hard enough I would be finished by summer.' (Farsi-Eng; Mahootian, 1993)

(46) elle te pique min fuq le drap
it bites you through the sheet
'it bites through the sheet' (Mor. Ar-Fr; Bentahila and Davies, 1983)

(47) Where are they, los language things?
_____, the _____
'Where are they, the language things?' (Sp-Eng; Poplack, 1980)

In sentence (45), a Farsi complementizer appears between an English main clause and an English embedded clause. In (46), a lone Arabic preposition appears in the midst of a French sentence. In (47), a Spanish determiner occurs in an all-English sentence.

In each case, the model would designate the language of the closed class item, i.e., the complementizer/preposition/determiner, as the matrix language, regardless of the fact that the rest of the sentence is syntactically and lexically in another language. Despite these problems, the main insights motivating this model remain valuable: that a third grammar for switching is unnecessary; and that switching results from the interaction between two grammatical systems with comparable categories.

The Government Constraint Di Sciullo *et al.*'s Government Constraint Model (1986) was an attempt to account for switches found between languages with dissimilar phrase structure rules, such as Hindi, Farsi, Japanese (SOV), and English (SVO). In this model, switching is prohibited where there is a government relation at S-structure between two elements. They propose that elements in a government relation must be in the same language, designated by the language index *q* such that: if X governs Y, $\ldots X_q \ldots Y_q$ (5). Y is a maximal projection, not a terminal node. The language index is assigned to the highest lexical element in a maximal projection. Government is defined through immediate c-command. For example, in the prepositional phrase *to school*, the preposition and its complement would both bear the index *q*, and would have to be in the same language:

(48)

In the phrase *to the school*, however, the determiner *the* is the highest lexical element in the governed DP *the school*, and will therefore be the language index carrier: *to* and *the* must be drawn from the lexicon of the same language, *school* may or may not be in another language. Example (49) illustrates:

(49)

This model successfully eliminates word order equivalence as a criterion for switching and allows for code switching between languages with dissimilar word orders. However, a number of conceptual and empirical problems have been noted. First, the notion of language index that the model rests on is, from a processing point of view, redundant and pointless for the monolingual speaker who may never be exposed to another language. More importantly, the Government Constraint proves to be too strong. The model predicts that switches between a verb (V) and COMP are prohibited, as shown in the Hindi/English examples (50) and (51) from Di Sciullo *et al.* (1986: 17):

(50) I told him that ram bahut bimar hai.
_____ Ram very sick AUX
'I told him that Ram was very sick.'

(51) *I told him ki ram bahut bimar hai.
_____ that Ram very sick AUX
'I told him that Ram was very sick.'

However, as the Farsi-English examples in (52) and (53) illustrate, switches do occur between V and COMP. Farsi, like Hindi, is an SOV language.

(52) I was implying ke in kar dorost nist.
_____ that this act correct isn't
'I was implying that this isn't right.'
(Mahootian, 1993: 104)

(53) They don't know ke noh noh-ta haeštad-o yek-e.
_____ that nine nine-CLASS eighty-and one-is
'They don't know that nine times nine is eighty-one.'

They also predict that conjunctions such as *and* or *but* will be in the same language as the clause being joined, so we should get CPq CONJp CPp, but we would not get *CPq CONJq CPp. However, this prediction does not hold true. Examples (54) and (55) show switching between a Farsi conjunction and the following English CP conjunct, and an English conjunction followed by a Farsi CP, respectively.

(54) fekr kaerd-aem daest-aem
thought did-1st hand-1stPOS
daerd begire vaeli it was fine.
pain get-3rd but _____
'I thought my hand would hurt but it was fine.'

(55) They are boys and morteza xeyli adaem-e- smart-i-ye.
____ morteza very person-EZ____ IND-is
'They are boys and Morteza is a very smart person.'

Halmari (1997) modifies and expands the Di Sciullo *et al.* model to accommodate Finnish-English code switches. In doing so, she strengthens the model and makes the apt observation that the Government model is likely one of a number of models that can account for **some** of the structural outputs of code switching.

The Functional Head Constraint Belazi *et al.* (1994) propose a model that restricts switching between a functional head and its complement: a functional head f-selects its complement with regards to

language as a feature, thereby ensuring a match between the language of the functional head and its complement. Accordingly, switching is disallowed between C and IP, I and VP, Neg and VP, D and NP, and Q and NP. Additionally, to account for noun/adjective switches, they posit the Word-Grammar Integrity Corollary, according to which words from a given language must obey the grammar rules of that language and no other. So, for example, postnominal modifiers cannot occur pronominally in a mixed utterance. The Functional Head Constraint model is similar to the Government Constraint model. Both rest upon and exploit a special relationship between certain elements (government/f-selection) and stipulate a language-sensitive component (language index/language feature) as part of the relationship. From this point, the two analyses turn in opposite directions from each other, resulting in a striking (near-) complementary distribution between Di Sciullo *et al.* and Belazi *et al.*'s analyses. What the government constraint rejects as switch points becomes fertile switching grounds for the functional head constraint.

Examples (56)–(59) show reported switches that violate the Functional Head Constraint.

C and IP
(56) il croyait bi?ana je faisais ça exprès.
he thought that I was doing that on purpose
'He thought that I was doing that on purpose.'
(Mor. Ar.-Fr; Bentahila and Davies, 1983)

I and VP
(57) Ní dispute-alfaidh mé leat.
neg ____-FUT I with-you
'I won't dispute with you.' (Ir-Eng; Stenson, 1990: 180)

Neg and VP
(58) Pára que no talfenéen a la mištará.
so that NEG. phone they would to the police
'So that they wouldn't phone the police.'
(Hebr-Sp; Berk-Seligson, 1986)

D and NP
(59) Ha portato un cadeau.
(he) brought a present
'He brought a present.' (It-Fr; Di Sciullo *et al.*, 1986)

Q and NP
(60) Daban unos steaks tan sabrosos.
(they) served some ____ so tasty
'They served some steaks so tasty.' (Sp-Eng; Pfaff, 1979)

Code-Switching Models Based on Universal Principles with No Special Mechanisms

In the early 1990s two new models emerged. One makes use of a fundamental principle of grammar, the Head-Complement Principle, to account for intrasentential switches as well as word-internal switches. (Mahootian, 1993, 1996a,b; Mahootian and Santorini, 1996). The other, the Matrix Language Frame model, relies on a matrix/embedded relationship between the speaker's two languages and on the distinction between system and content morphemes. (Myers-Scotton, 1993, 2002).

The MLF Model The Matrix Language Frame (MLF) model for code switching (Myers-Scotton, 1993, 2002) explains code switching in terms of two types of asymmetry: (a) the Matrix Language (ML) vs. the Embedded Language (EL) and (b) content vs. system morphemes. System morphemes overlap with the members of the category traditionally referred to as closed-class items. They carry the feature [+Quantification]. System morphemes can be specifiers, quantifiers, possessive adjectives, and inflectional morphemes. Content morphemes have the feature [−quantification] and are the morphemes that assign or receive thematic roles. They may be either in the ML or the EL. Content morphemes can be verbs, nouns, descriptive adjectives, or prepositions.

The MLF model rests on four hypotheses (Meyers-Scotton, 1993): the Matrix Language Hypothesis, the Blocking Hypothesis, the Embedded Language Island Trigger Hypothesis, and the Embedded Language Implicational Hierarchy Hypothesis.

1. The Matrix Language Hypothesis: the grammatical frame in intrasentential code switching is set by the matrix language. This hypothesis is guided by two principles. The Morpheme Order Principle states that, in a mixed constituent, morpheme order cannot violate the order of morphemes in the ML. The System Morpheme Principle states that the ML supplies the system morphemes in mixed constituents.
2. The Blocking Hypothesis: switching is blocked when content morphemes from the embedded language do not meet ML congruency requirements.
3. The Embedded Language Island Trigger Hypothesis: switching into a nonpermissible EL morpheme forces an obligatory EL island, i.e., the constituent must be completed in the EL.
4. The EL Implicational Hierarchy Hypothesis: idiomatic, formulaic, or peripheral EL constituents may occur and will not be barred by hypotheses 1, 2, or 3.

In the mixed constituents in examples (61)–(62), Irish and Finnish are considered the matrix languages.

(61) Ni *disput*alfaidh me leat
neg dispute-FUT I with-you

'I won't dispute with you' (Ir-Eng; Stenson, 1990)

(62) Se oli semmosesta *land*istä.
it was such +ELAT ___ +ELA
'It was about a land.' (Finn-Eng; Halmari, 1997

In her revised MLF model, the 4-M model, Myers-Scotton (2002) makes finer distinctions between system and content morphemes. The 4-M model defines subtypes of system morphemes, arguing that while this basic dichotomy holds, the subtypes of morphemes have both explanatory and predictive power.

The general objection brought against the MLF model has to do with its reliance on the matrix-embedded distinction. As discussed earlier, this distinction is not clearly defined. Although the MLF's first hypothesis is intended to systematize this distinction, it has been noted that the description contains a certain amount of circularity: on the one hand, the ML is recognized by the fact that system morphemes are in the ML. On the other hand, the System Morpheme Principle specifies that system morphemes are supplied by the ML. Thus, examples such as (63)–(65) would either have to be noted as counter-evidence to the model or one must in each instance assign ML status to the entire utterance based on a single morpheme.

(63) Anyway I figured *ke* if I worked hard enough . . .
_____ that _____
'Anyway I figured that if I worked hard enough . . .' (Farsi-English; Mahootian, 1993)

(64) there wasn't an item *vos* we didn't have
_____ that _____
'there wasn't an item that we didn't have' (Eng-Yidd; Prince and Pintzuk, 1984)

(65) Lawyer-*et* will tell you what to do.
_____ 2P-POSS _____
'Your lawyer will tell you what to do.' (Farsi-Eng; Mahootian, 1993)

The Head-Complement Principle Model The Head-Complement Principle model followed in the footsteps of earlier researchers such as Bentahila and Davies and Woolford in looking for a principle-based approach. The model sets out to account for the multitude of switches recorded between typologically dissimilar languages and for switches found between bound and free morphemes. The model builds on three basic assumptions:

1. The same principles and derivational constraints that produce monolingual utterances produce mixed utterances, whether the switch involves a bound morpheme, a single word, or an entire phrase. General principles of phrase structure, rather than constraints specific to code switching, produce code switched utterances.
2. No special third grammar is needed to account for code switched utterances. A bilingual's two grammars are sufficient to generate code switching. The two grammars remain distinct, both sociolinguistically and syntactically. Their interaction is accounted for by (1).
3. From a syntactic perspective, there is no formal distinction between 'code switching' and 'borrowing': both can be accounted for in the same way by the same principles of grammar.

The principle itself is summed up below (Mahootian, 1994, 1996a,b):

> The Head-Complement Principle (HCP): heads determine the syntactic properties of their complements in code switching and monolingual contexts alike: heads determine the phrase structure position, syntactic category, and feature content of their arguments.

The HCP applies to both lexical and functional heads. Consequently, switches are permissible between determiner (including Quantifiers) and NP, Comp and IP, Infl and VP, V and PP, P and DP, and other heads and their complements. Furthermore, single-word switches and within-word switches, often treated as borrowings and therefore left outside of syntactic analysis, are accounted for in the HCP model.

In the HCP model, maximal projection nodes are the points at which switching occurs: switching may occur where there is phrase structure **label** congruence between languages. This is different from previous approaches that rely on word-order congruence between the switching languages.

In line with numerous theories of grammar where the lexicon plays a central role, this model adopts a view of grammar where the lexicon projects phrase structures. Lexical items of a language are represented as trees reflecting their language-particular syntactic requirements in accordance with X-bar theory. This view of language as a combination of structures rather than strings allows for switches between languages with dissimilar word order that other approaches have not been able to address. The HCP model predicts:

- switches at all maximal projections (possible but not obligatory),
- L1 word order with mixed L1/L2 words,
- L2 word order with mixed L1/L2 words,
- L1 word order with all L1 words,
- L2 word order with all L2 words.

Application of the model is illustrated with the Farsi-English object-verb switch in (66). Farsi is an SOV language.

(66) ten dollars dad
_____ gave
'she gave ten dollars'

Based on the assumptions of the model, the utterance in (66) is derived from the Farsi structures shown in (67) and the English structures shown in (68).

(67)

(68)

Lexical items project the structures in (67a)–(67d) and (68a)–(68d). The combination of the tree in (68b) + (68c) + (68d) yields the DP structure in (69). This DP combines with the lexical structure for *dad-e* 'gave', to yield a Farsi left-branching VP, *ten dollars dad*, shown in (70).

(69)

(70)

Given the assumptions of this model, the same lexical structures generate comparable monolingual utterances in Farsi and English. By combining phrase structures (67a)–(67d), we get the Farsi utterance in (71).

(71) daeh dolar dad
ten dollar gave
'gave ten dollars'

A combination of (68a)–(68d) yields the English phrase in (72):

(72) gave ten dollars

A number of other attested types of mixed utterances can also result from the phrase structures in (67) and (68), for example, gave daeh dolar, gave daeh dollars, ten dolar dad. Switches across morpheme boundaries are accounted for in the same manner.

The HCP model has some clear advantages over models that require mechanisms and rules specific to code switching. By applying principles of universal grammar, the model accurately predicts switch points at clause, phrase, and within word levels. No additional mechanisms or assumptions are required.

MacSwan (1999), inspired by the simplicity and broad scope of application inherent in the HCP approach, recast the same insights and principles into a minimalist framework.

Bilingual Language Acquisition and Code Switching

'Bilingual language acquisition' refers to the simultaneous acquisition of more than one language during the developmental stages of language acquisition. One of the first documented studies of this process was conducted by Ronjat (1913), who examined his son's simultaneous acquisition of German and French. This was followed by a number of other longitudinal studies. Of particular significance is Leopold's seminal four-volume detailed diary of his daughter's acquisition of German and English (Leopold, 1939–1949). Leopold's study marked the beginning of focused interest in child bilingualism. Since then, numerous other studies have been conducted in this area.

One of the issues arising from research into child bilingualism is the status of code switching. The main theoretical question for researchers in this area is whether children start out with a unitary language system that gradually splits into two separate systems or whether they start out with two separate systems. Proponents of the unitary system contend that the words of both languages form a single lexicon for the child and that mixed utterances at the two- and three-word stage support a nondifferentiated system. Researchers supporting the separate system, also called the Independent Language Hypothesis, maintain that children start out with two separate systems and keep them differentiated. They show that children typically keep their languages separated when they are in monolingual contexts by using the appropriate language for the context. To show an undifferentiated system, they assert, a child would need to use the two languages randomly in either context.

Another question regarding language mixing in early acquisition stages concerns the similarity between the types of switches found in children's utterances and those found in adult switches. Structurally, the question is whether children mix their two languages in the same way adults do. The answer to this question has theoretical implications on a number of fronts. One much debated issue in first language acquisition is whether adult grammars are a continuation of children's grammars or if the two are separate systems. The similarity between adults' and children's code switches may bear on this question in particular, and on the notion of language universals in general.

A further insight gained from child code-switching data concerns existing models of code switching. How well do these models hold up when they set out to account for children's code switches? Of the existing models, only a few, Mahootian's HCP model and Myers-Scotten's MLF model, have been successfully applied to children's code-switching data.

Examples (73)–(77) show mixed utterances produced by children. Children's ages are noted in parentheses in years followed by months. Languages are abbreviated as follows: Fr = French, Germ = German, Russ = Russian, Norw = Norwegian.

(73) ça ça sonne (1;11, Fr-Germ; Köppe and Meisel, 1995)
this this sun

(74) das dort ne? (2;0, Germ-Fr; Köppe and Meisel, 1995)
this sleeps, right?

(75) mer cookie (2;2, Norw-Eng; Lanza, 1997)
more ____
'more cookie'

The following is a comparison between adult mixed utterances and children's mixed utterances showing switches occurring at the same grammatical junctures (Mahootian, 1999).

- Switches between Determiner and NP

(76) el same night
the _____
'the same night' (adult: Sp-Eng; Pfaff, 1979)

(77) That's my kino.
_____cinema (movie)
'That's my movie.' (child: 3; 4, Russ-Eng; O'Neill, 1998)

- Switches between Verb and DP

(78) il ne faut pas changer ttwSe:*l*
_____ the receipt
'You must not change the receipt.' (adult: Arab.-Fr; Bentahila and Davies, 1983)

(79) klappe hand
clap _____
'clap hand' (child: 2; 2, Swed.-Eng; Lanza, 1997)

- Switches between Subject DP and I′

(80) No you govorish, chto eto vozmozhno.
But _____ say that that possible
'But you say that it's possible.' (adult: Russ-Eng; O'Neill, 1998)

(81) Jeg give it to Daddy
I _____
'I give it to daddy' (child: 2; 7, Norw-Eng; Lanza, 1997)

- Switches between V and PP

(82) Nu vidish, Steven King zhil in a trailer.
well you see _____ lived _____
So you see, Steven King lived in a trailer.' (Adult: Russ-Eng; O'Neill, 1998)

(83) on va maintenant zum krankenwagen
we go now to the ambulance
'We now go to the ambulance.' (child: 3; 7,2, Germ.-Fr; Meisel, 1994)

- Switches between Roots and Affixes

(84) Eto na dresser-e.
That on _____-LOC-Sg
'It's on the dresser.' (adult: Russ-Eng; O'Neill, 1998)

(85) It's lop -en.
__ break-____
'It's broken.' (child: 3; 10, Russ-Eng; O'Neill, 1998)

Coelho, Francisco Adolpho (1847–1919)

R Cavaliere, Universidade Federal Fluminense, Rio de Janeiro, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Francisco Adolpho Coelho is the most important 19th-century name in the field of Portuguese linguistic studies. He was born in Coimbra on January 15, 1847, and died in Carcavelos on February 9, 1919. Coelho distinguished himself as an extraordinary, self-taught person during his basic education, although it is known that he had attended classes at the University of Coimbra between 1862 and 1864. In Lisbon, Coelho entered the university as a student of the Superior Course of Letters, in which he studied at least from 1865 till 1866. In 1878, he began his career as an assistant professor in this same course, teaching general Indo–European linguistics. Due to Coelho's comparative research on Romance languages, the thesis presented to the academic word by Friedrich Diez in his *Grammatik der romanischen Sprachen* has been applied in modern Portuguese linguistic studies, and that is the reason why philology began to be studied by more qualified people in Portugal from that time on. His first published work, entitled *A língua portuguesa: fonologia, etimologia, morfologia e sintaxe* (1868), is thus considered the initial step of the historical–comparative school in Portugal.

Some years later, Coelho managed to publish two other important works about descriptive grammar based on the comparative method: *Theoria da conjugação em latim e portuguez. Estudo de gramática comparativa* (1870) and *Questões da língua portuguesa* (the first part in 1874 and the second in 1889). His bibliography, nevertheless, is not absolutely restricted to the field of linguistics, since he had written

level. Code-switching is common in the young generation. This generation is also particularly exposed to standard Indonesian and standard Malay. The exposure to Indonesian comes from the media (Indonesian TV) as well as from Bahasa Indonesia, which is offered in school as a second language choice. The influence of Malay comes less directly, from the status that the language enjoys for literary and religious reasons: in 2001 there were clearly normative voices to be heard advocating a more standard form of Malay to be spoken on the island. All these facts considered, it is quite likely that Cocos Malay may lose many of its particular traits in the near future.

Cocos Malay communities can also be found in Western Australia (children have to move there to complete their education after grade 10) as well as in Sabah, Malaysia. Relocated from the original settlements in different waves as the islands can only sustain a limited population, these communities are described as having lower proficiency in Cocos Malay than that on Home Island. In particular, in Sabah it is reported that convergence towards standard Malay has taken place.

Codes, Elaborated and Restricted (Bernstein)

A Capone, Barcellona, Italy

© 2006 Elsevier Ltd. All rights reserved.

Bernstein was among the first scholars to focus on the correlation between the scholastic success (or failure) of a learner and the social class he or she belonged to. A student living in a well-off family, having many cultural stimuli (books, newspapers, periodicals, films, etc.) is bound to develop a rich and fully articulated language (a so-called 'elaborate code'), whereas a student who belongs to a working-class family and is exposed to poor linguistic and cultural stimuli, develops a fragmented, poor, syntactically deficient language (called a 'restricted code' by Bernstein) (see Bernstein, 1971–1975).

Contrary to the Chomskyan theory that language naturally develops in the brain, due to the interaction of biologically innate structures and the environment to which the child is exposed, may be that the data to which the child is exposed are so poor and confused that it is easy to demonstrate that the innate learning program prevails over the environmental stimuli, Bernstein emphasizes the predominant role played by the environment in shaping the learning process. Of course, the correlation between social class is not, strictly speaking, without exceptions, because much of the learning process depends on the lifestyle of the family under consideration. There are exceptional working-class families where parents, contrary to all expectations, have good knowledge of the language and place great importance on culture, but the norm is that, within working-class families, cultural stimuli are less predominant than in more well-off families.

The problem, for sociologists, is how to offset the disadvantages of the pupils belonging to working-class families and how pedagogues (and teachers) can have an antideterministic effect on such children.

A possible solution to the problem is to ensure that the school (or the class) becomes another miniature family and that the negative effects of the families are compensated for by the pedagogical action of the school. The school should, therefore, be a positive environment in which pupils are exposed to positive cultural and affective stimuli that help their personalities grow and come to maturity. In such a model of the school, teachers lose their primary function of being transmitters of notions (knowledge, in general) and are required to take the roles of educators or pedagogues who act as models and provisionally replace (at least within the boundaries of the school) the family by setting good examples for the students, and, in particular, exposing them to the positive aspects of culture, intended as knowledge that interacts with the

individual to make him or her grow up intellectually and emotionally. To compensate for the negative effects of families, within which dialogue and conversation have died, or are confined to adjacency pairs consisting of questions/answers or orders/replies, teachers have to play the role of communicators and have to stimulate communication. It is, in my view, impossible for a student to make progress in his or her language (to develop a more articulated written or oral mode of expression) unless he or she understands the function of communication, which is that of transmitting knowledge, but also of enhancing the expressive as well as the interpersonal function. To communicate is not only to express propositions (concerning others), but also to express propositions concerning what we really are and feel, and, by so doing, to interact with others, creating an intersubjective dimension in which social life is possible (see Capone, 2003).

Code Switching

S Gross, East Tennessee State University, Johnson City, TN, USA

© 2006 Elsevier Ltd. All rights reserved.

In many bi- and multilingual communities around the world, speakers need to choose, often at an unconscious level, which language to use in their interactions with other members of the community. One of the choices that bilingual speakers often make is to code-switch: that is, speakers switch back and forth between languages (or varieties of the same language), sometimes within the same utterance (*see* **Bilingualism; Code Switching and Mixing**).

The motivations for code switching have often been treated simply as lists of possible functions for code switching. For example, Appel and Muysken (1987) cite five such functions. First, code switching may serve a referential function by compensating for the speaker's lack of knowledge in one language, perhaps on a certain subject. Second, it may serve a directive function by including or excluding the listener. Third, code switching may have an expressive function by identifying the speaker as someone having a mixed cultural identity. Fourth, it may have a phatic function indicating a change in tone in the conversation. And fifth, it may serve a metalinguistic function when code switching is used to comment on the languages involved.

While such lists are useful places to start, and no one would deny that code switching can certainly serve these functions, these types of lists fail to answer the question of what motivates speakers to make the choices they do at a particular point in a conversation. This article reviews the major proposals that have been advanced regarding the following question: why do speakers choose to engage in code switching in the first place?

Code Switching as a Research Topic

The current interest in code switching can be dated to a 1972 study of language use in Hemnesberget, a small village in northern Norway, conducted by Jan Blom and John Gumperz and described in a volume on sociolinguistics edited by Gumperz and Hymes (1972). In Hemnesberget, two varieties of Norwegian are used: Ranamål, a local dialect, and Bokmål, the standard variety (*see* **Language and Dialect: Linguistic Varieties**). However, speakers' decisions regarding which variety to use are by no means arbitrary or haphazard. In general, Ranamål, the local variety, is used in local activities and relationships, reflecting shared identities with the local culture. In contrast, Bokmål is used in official settings such as school, church, and the media, communicating an individual's dissociation from the local group, i.e., not stressing his or her local ties.

Blom and Gumperz distinguish between two main functions of code switching: situational and metaphorical. In situational code switching, which seems to be similar to the notion of diglossia, the speaker's choice of language is constrained by factors external to her/his own motivations, for example, the status of the interlocutor, the setting of the conversation, or the topic of conversation. So, in Hemnesberget, Blom and Gumperz observed that when an outsider joins a group of locals engaged in a conversation, the locals will often switch from the local variety, Ranamål, to the standard variety, Bokmål. In a later work, Gumperz (1982) introduces the distinction between 'we' and 'they' codes, which further

Coelho, Francisco Adolpho (1847–1919)

R Cavaliere, Universidade Federal Fluminense, Rio de Janeiro, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Francisco Adolpho Coelho is the most important 19th-century name in the field of Portuguese linguistic studies. He was born in Coimbra on January 15, 1847, and died in Carcavelos on February 9, 1919. Coelho distinguished himself as an extraordinary, self-taught person during his basic education, although it is known that he had attended classes at the University of Coimbra between 1862 and 1864. In Lisbon, Coelho entered the university as a student of the Superior Course of Letters, in which he studied at least from 1865 till 1866. In 1878, he began his career as an assistant professor in this same course, teaching general Indo–European linguistics. Due to Coelho's comparative research on Romance languages, the thesis presented to the academic word by Friedrich Diez in his *Grammatik der romanischen Sprachen* has been applied in modern Portuguese linguistic studies, and that is the reason why philology began to be studied by more qualified people in Portugal from that time on. His first published work, entitled *A língua portuguesa: fonologia, etimologia, morfologia e sintaxe* (1868), is thus considered the initial step of the historical–comparative school in Portugal.

Some years later, Coelho managed to publish two other important works about descriptive grammar based on the comparative method: *Theoria da conjugação em latim e portuguez. Estudo de gramática comparativa* (1870) and *Questões da língua portuguesa* (the first part in 1874 and the second in 1889). His bibliography, nevertheless, is not absolutely restricted to the field of linguistics, since he had written

many well-recommended texts about literature and popular traditions. In this area, Coelho organized several editions of popular Portuguese short stories and texts for youths. His name is linked as well to ethnographic and anthropological research, with texts written under the brilliant knowledge of the 19th-century ethnolinguists, such as *Exposição Etnográfica Portuguesa* (1896) and *Os Ciganos de Portugal;com um estudo sobre o calão* (1892). Inspired by Hugo Schuchardt's ideas about dialects and creole languages, Coelho proceeded with an exhausting investigation about Portuguese-based African and Asiatic creoles, in addition to having published some studies on Brazilian Portuguese (that, in his conception, should be called Brazilian dialect). This segment of his bibliography has been severely censured by some philologists of his time, such as José Leite de Vasconcelos, who reproached these papers for being the product of desk work only due to the fact that Coelho didn't endeavor to develop field research methods. It is imperative to attribute to Coelho the virtue of renovating the linguistic thought in his country, whose bases still were, by the middle of the 19th century, immersed in the rational ideas of philosophical grammar. This revolutionary trend contributed decisively to a new order in the teaching of vernacular language in elementary and middle levels. According to the Brazilian linguist Serafim da Silva Neto, Coelho "has been a philosopher-philologist, with the faithful purpose of ascending to general ideas." Undoubtedly, his activity in the 19th century linguistic scene opened the doors of Glottology and Ethnolinguistics to those who dedicated themselves to the study of the Portuguese language, and even to the study of the Romance languages in general, creating a great legion of disciples not only in Portugal but also in Brazil.

Cœurdoux, Gaston-Laurent (1691–1779)

K Karttunen, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

The French missionary and pioneer of Indology Gaston-Laurent Cœurdoux was born in Bourges, France, in 1691 and died in Pondicherry in the colony of French India in 1779. He joined the Jesuit order in 1715, departed for South India in 1732, and served as a member of Madurai Mission until his death. In 1744 he was named superior of the mission, a role he filled until 1751. Beside his missionary work, he showed keen interest both in science and in language studies. In addition to local Dravidian languages (Tamil and Telugu), he learned Sanskrit and was one of the first to note its resemblance with classical Greek and Latin (and German). In a well-known memoir, he demonstrated the relationship between Sanskrit and European languages well before Sir William Jones; he sent the text to Anquetil-Duperron to Paris for publication, but it remained in manuscript form and was printed only at the beginning of the 19th century (in *Histoire et Mémoires de l'Académie des Inscriptions et Belles-Lettres 49*, 1808: 647–667). Another work by Father Cœurdoux, a detailed account of South Indian customs, remained unpublished and was to a large extent copied by Abbé Dubois in the book he then published under his own name (published in French in 1825, in English translation 1817, rev. ed. *Hindu manners, customs and ceremonies* 1897). The original version is preserved in an abridged version that was published in 1987 by Sylvia Murr, who also showed Dubois's complete dependence on it. There are further some letters by Cœurdoux published in *Lettres édifiantes et curieuses,* a manuscript dictionary 'télougou–français–samskroutam [i.e. Sanskrit],' and some further manuscript works.

Cognitive Anthropology

C Strauss, Pitzer College, Claremont, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Cognitive anthropology is the study of cultural knowledge and processes of cognition in a sociocultural context. While most cultural anthropologists study cultural knowledge, cognitive anthropologists do so distinctively by asking how specific people in a society think. Cognitive anthropology dates from the late 1950s, although there were many earlier precursors (e.g., the work of Evans-Pritchard).

In cognitive anthropology today, major schools can be distinguished by their answers to two questions. First, does the cultural part of cognition (D'Andrade, 1981) consist of mental representations or situated practices? Second, how significant are panhuman cognitive universals?

Cultural Cognition as Culturally Variable Mental Representations

An early, influential statement of this approach, cultural cognition as cross-culturally variable mental

representations, is Goodenough's definition of a society's culture as "whatever it is one has to know or believe in order to operate in a manner acceptable to its members" (Goodenough, 1957: 167). From Goodenough on, language has been central to work in this approach, as both evidence for and the content of cultural knowledge, and linguistics has been an ongoing source of theoretical inspiration.

From the 1950s through the 1970s, a major focus of research was lexical semantics ('ethnosemantics'). Typically, all of the terms in a domain (e.g., kin terms, kinds of talk) are elicited, then an underlying mental structure of defining or salient features is inferred from contrasting patterns of use or judgments of similarity. Influenced by phonologists' decomposition of sounds into distinctive features, componential analysts similarly analyzed word meanings as sets of semantic features (e.g., BACHELOR = +MALE, −MARRIED). Systematic methods were developed for eliciting terms and their relations (e.g., frame and slot elicitation: What words can fill the blank in a sentence like, "____is a kind of sport," or pile sorts and triads tests, analyzed with multidimensional scaling, Weller and Romney, 1988). Work in this tradition sometimes focused on biological classifications and was called 'ethnoscience'; however, that term covers later folk science studies using other methods as well.

One current development of such work is the study of cultural knowledge as consensus in responses to standardized questions (Romney and Moore, 1998; Romney *et al.*, 1986). Cultural consensus analysis can be used to determine patterns of disagreement as well as consensus, which can highlight the social distribution of knowledge (see, e.g., Boster's 1985 study of the effect of kinship and residence on Aguaruna women's knowledge of manioc varieties).

While these methods have been extremely productive, a number of concerns arose about the older, lexically focused methods (these objections do not all apply to cultural consensus modeling). It was not always clear that the analyst's structures corresponded to the mental representations of members of the society in question; in some domains, a study of key terms reveals only problematic cases, not the taken-for-granted normal scenario (Holland and Skinner, 1987); in many cases, lexical semantics omits crucial elements of cultural knowledge (e.g., eliciting meanings of disease terms in English will not reveal a germ theory of disease, D'Andrade, 1995); and distinctive features are not random assortments of attributes, but co-occur in patterned wholes, as discussed by Rosch and others (see summary in D'Andrade, 1995). Schema theory was adopted from the work of linguists such as Fillmore and Langacker and psychologists (e.g., Schank and Abelson) to address these issues. Schemas ('frames') are mental representations of an underlying, typical pattern of features or connected set of ideas understood holistically. For example, my MINIVAN schema includes not only the features that distinguish it from other vehicles, but also a mental image and ideas about what sort of person is likely to drive one. Shared schemas are cultural models (Holland and Quinn, 1987). A speaker's reference to one part of a cultural model will activate the whole schema, as well as related schemas, in a listener's mind; hence, much can be left unsaid when culture is assumed to be shared. Cultural model researchers typically conduct in-depth, semistructured interviews, inferring the implicit understandings that are assumed in what is said (Holland and Quinn, 1987; Quinn, in press).

While the focus of work in this approach has been on contents of cultural knowledge, some researchers have addressed cognitive processes and the way knowledge is used: e.g, in memory and personal narratives (e.g., Garro, 2000; see also memory research in studies of linguistic relativity), metaphor choice (Quinn, 1991), the pragmatics of opinion expression (Strauss, 2004), reasoning (Hutchins, 1980; Quinn, 1996), and motivation (D'Andrade and Strauss, 1992). Connectionist models have been proposed to address how cultural knowledge, including nonpropositional knowledge, is learned, changes, and is sensitive to the context of its use (Strauss and Quinn, 1997).

Cultural Cognition as Situated, Distributed Practices

Cognitive processes, rather than cultural knowledge, dominate the work of cognitive anthropologists who study distributed cognition or 'cognition in practice.' They argue that studies in the first school neglect emergent cognitive effects as people interact with each other and the objects and structures in their environment. Thus, the primary method employed here is observation of ongoing activities (arithmetic while shopping, Lave, 1988 or navigation on board a ship, Hutchins, 1995), perhaps asking the person being observed to think out loud while they are in the midst of their activity. Drawing on Marxian psychology (e.g., Vygotsky, and Leontiev's Activity Theory), some argue that a key way cognition is 'cultural' is that it depends on tools or 'mediating devices': concrete objects, symbols, and activities that are socially produced, and which evoke and

direct thought (Holland and Valsiner, 1988). One example is Goody's argument that the invention of writing, especially lists and tables, created the possibility for new structures of thought (but see Scribner and Cole, 1981 on the cognitive effects of the Vai script in Liberia). The means and social relations of communication are also relevant 'structuring resources' (Lave, 1988). Hutchins (1995), for example, considered how the bandwidth of communications media, the social ranking of who talks to whom, and the timing of their talk affect the propagation of cognitive representations among the members of a navigation team on a large ship (see Nardi, 1996 for a useful comparison of different cognition-in-practice approaches).

Universals in Human Cognition

Other cognitive anthropologists agree with the first school in its focus on mental representations but disagree with its emphasis on cross-cultural variability. Thus, for example, Berlin and Kay (1969; Kay *et al.*, 1997) analyzed basic color terms (ones that are monolexemic like 'red,' not subtypes of another color, etc.) first in 20, then in 110 languages. They found a restricted set of basic color terms with cross-culturally stable focal referents, and comparable composite color categories across all languages. In addition, there is a fairly predictable relation between the number of basic color terms in a language and which colors are named. Atran (1990) and Berlin (1992) observed cross-cultural and historical similarities in classification of plants and animals. Lately, empirical studies have been joined by theories prioritizing cognitive universals. These draw on Chomsky and Fodor's claims that human brains process much information with specialized modules, and those of evolutionary psychologists that human brains are the result of evolutionary adaptation during the Pleistocene, thus include innate knowledge and processing rules that are useful for social cooperation and categorization, mate selection, foraging, and predator avoidance (Cosmides, 1989; Hirschfeld and Gelman, 1994, but see criticisms by Donald, Karmiloff-Smith and others). The research on cross-cultural cognitive universals challenges extreme claims of linguistic relativity.

Directions for the Future

Theoretical bridges have been proposed between cultural models and practice theory; thus, Holland and Valsiner (1988) argued that learned schemas determine the purposes to which mediating devices are put, Keller and Keller (1993) studied feedback between external events and internal representations over the course of an extended activity, and Quinn (1996) argued that cultural models are internal mediating devices. Similarly, cognitive anthropologists in the first and last schools would agree that there are both universals and variation in cultural knowledge (see, e.g., D'Andrade, 1995; Romney and Moore, 1998; Sperber, 1985; Strauss and Quinn, 1997); the only question is of what sorts. An underexplored issue is differences in ways of knowing (Sperber, 1985; Strauss and Quinn, 1997: Chap. 8). Finally, an interest that cuts across all three approaches is what Sperber (1996) called the "epidemiology of representations": how ideas spread among people in groups, how they are transformed, and how they are used as they move between internal and external forms (Hutchins, 1995; Keller and Keller, 1993; Strauss and Quinn, 1997).

Cognitive Basis for Language Evolution in Nonhuman Primates

R Tincoff and M D Hauser, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

A defining feature of the human language faculty is its limitless capacity for expressing ideas. We can produce an infinite number of new sentences, and we can compose sentences of infinite length. This ability reveals a powerful computational mechanism, a form of recursion often termed **discrete infinity**. This recursive mechanism entails a procedure or rule that calls itself, specifically, combining the discrete store of words or sentence constituents (e.g., Noun, Verb) into hierarchical phrase structures that can be further embedded within other hierarchically arranged phrase structures. Computational mechanisms are also involved in generating phonological and semantic representations, as well as in the interfaces among syntax, phonology, and semantics. Here we focus on the language faculty and its evolution in terms of these internal computational mechanisms instantiated in the mind/brain of each language user. This focus is conceptually separate from concerns about the actual production and social use of language and leads to a particular set of questions about language evolution.

The significance of recursion for generating linguistic representations and mapping between interfaces leads to the proposal that such a device must be universal to all human languages and innately endowed in human infants (Lenneberg, 1967; Chomsky, 1988). These features, **universal** and **innate**, raise an important question: how did our language faculty evolve? Specifically, do phylogenetic analyses reveal precursors to the language faculty in other animals? This specific question is distinct from, but complementary to, other approaches to studying language evolution that consider historical or cultural factors or employ mathematical models of potential evolutionary scenarios (for a variety of approaches see chapters in Christiansen and Kirby, 2003). In addition, this question reflects a starting assumption that, in the absence of hearing deficits, spoken language is the default output form of the language faculty. Comparative studies complement this starting assumption as our knowledge of other species' communication systems is largely based on ones using the vocal-auditory channel (Hauser and Konishi, 1999). Additional methods will be necessary to explore the language faculty as expressed by signed languages, and to explore questions about why human language has flexibility in its expressive form, an additional defining feature that is lacking in nonhuman communication systems.

Below, we describe why data from nonhuman animals, particularly nonhuman primates (hereafter 'primates'), are critical for explaining the patterns and processes of language evolution. The general conclusion we draw is that once the language faculty is separated into its component systems, a wealth of opportunities for comparative analysis opens up and yields interesting insights into the origins of human language (Hauser *et al.*, 2002).

Applying the Comparative Method of Evolutionary Biology to Language Evolution

Evolutionary biology provides a method for determining the phylogenetic origins of traits and their functions (for a detailed survey see Ridley, 2004). This method selects species that share a trait and then examines their evolutionary relationship. **Homologies** are traits with similar structure or function that have descended from a common ancestor; for example mammary glands used for lactation are shared by humans and rats, and by our common mammalian ancestor. Homologous traits are therefore derived from a common ancestor, tending to arise most frequently among closely related species. **Homoplasies** are traits shared by a pair of species, but not present in their common ancestor; classic examples include the eye, which has evolved independently in many different lineages, and the wing, which has evolved independently in birds and mammals. Homoplasies provide the signature of convergent evolution, and reveal the powerful role of selection in creating adaptive solutions to common social and ecological problems. Further comparisons of species will also reveal **phylogenetically novel** traits that appear in one species, or a cluster of species within a genus, and exhibit a particular structure or function. The comparative method allows researchers to lay out the terrain of shared and unique traits among selected species and then draw inferences about how those traits evolved (for applications to cognition and language see Gallistel, 1990; Shettleworth, 1998; Hauser, 2000; Hauser, 2003; Fitch, in press).

The evolution of language presents a particular set of problems to the comparative approach. First, there are no other living human species and thus we cannot follow the usual form of the comparative method, comparing living, closely related species sharing similar behaviors. Second, the record of early hominids is limited to fossil bits of vocal tract that provide few

insights into the computational machinery underlying what our hominid ancestors produced, while ancient written records essentially represent language in its modern form. Finally, no single nonhuman species is equipped with a sufficiently inclusive set of abilities to constitute a precursor to our full-blown language faculty, and some traits appear to be absent altogether (Hockett, 1960; Hauser, 1996; Hauser, 2000). How do we study language evolution when the human species is a poor model for the comparative method and other species do not offer an equivalent repertoire?

Distinguishing the Shared and Unique Components of the Language Faculty

In exploring language evolution from a comparative perspective, there are three possible outcomes for any given trait:

1. Trait X is not uniquely human, is a homology evolved for an earlier function, directly inherited, and therefore did not evolve for language;
2. Trait X is not uniquely human, but is a homoplasy that evolved completely unrelated to language or evolved for other purposes and was redesigned for language;
3. Trait X is uniquely human, is a phylogenetically novel trait that evolved only in hominid species, possibly for language or possibly for another cognitive capacity.

Hauser *et al*. (2002) lay out a comparative research program for explaining the evolution of the language faculty, separating it into a broad and a narrow sense. The faculty of language in the broad sense (FLB) encompasses the sensory-motor (SM) system responsible for perceiving and producing the sound patterns of spoken language, the conceptual-intentional (CI) system involving conceptual representations and the capacity to refer, and the faculty of language in the narrow sense (FLN). FLN is the recursive system responsible for the computations involved in narrow syntax that generate internal representations and it maps them into the systems of phonology (SM) and semantics (CI); importantly, then, FLN entails recursion and its interfaces with phonology and semantics. The strict definition of FLN and its separation from FLB, along with the available comparative evidence, motivated the proposal that "most if not all of FLB is based on mechanisms shared with nonhuman animals . . . [but] . . . FLN – the computational mechanism of recursion – is recently evolved and unique to our species" (Hauser *et al*., 2002: 1573). This proposal represents "a tentative, testable hypothesis in need of further empirical investigation" (Hauser *et al*., 2002: 1578).

This empirical program targets comparative studies aimed at distinguishing homologies, homoplasies, and phylogenetically novel mechanisms among the components of the language faculty. The data sets include nonhuman animals' natural communication, their noncommunicative problem-solving abilities, and their perceptual sensitivities to speech stimuli and the computational abilities that underlie language organization. The methodologies include field studies of natural behavior, laboratory studies building on those field studies, and, in the case of speech stimuli, combining the two such that researchers employ spontaneous behavioral measures borrowed from the field with carefully controlled laboratory methods. The goal of using speech stimuli, by definition artificial for primate subjects, is to assess whether they have the perceptual and computational abilities to extract the relevant dimensions such as phonetic categories, prosodic rhythms, word-like units, and grammatical structures. By employing the comparative approach, researchers can triangulate on the critical traits that contribute to the uniquely human form of language.

Evidence of Homologous Mechanisms

The sensory-motor system includes abilities used in vocal production, imitation, and auditory perception. Here we highlight studies of auditory perception as they provide strong evidence for homologous mechanisms shared by humans and primates (Trout, 2001; Hauser *et al*., 2002). Vocal production and imitation reveal a more complicated pattern of similarities and differences across species (Rizzolatti and Arbib, 1998; Fitch, 2000).

A classic set of findings reveals that categorical perception, required for detecting the articulatory-acoustic cues to phonetic boundaries, is shared between humans and primates, along with other mammalian and nonmammalian species such as chinchilla and quail (for reviews see Harnad, 1987; Hauser, 1996). These experiments entail carefully controlled laboratory methods with trained responses (e.g., shock avoidance, button pressing) and natural or synthetic speech stimuli to test the animals' discrimination of cues signaling the boundaries between phonetic categories. The general conclusion is that the animals' discrimination and labeling functions follow those detailed in studies of human adults and infants. For example, rhesus monkeys tested on a voice onset time contrast showed, similarly to humans, that they were most sensitive to differences close to the human phonetic boundaries and less sensitive to differences within a phonetic category. Laboratory and field studies of categorical perception using species-specific vocalizations, as opposed to speech, confirm

the general nature of this perceptual ability. These findings lead to the conclusion that categorical perception is shared among a broad range of species and represents a general as opposed to a speech-specific perceptual capacity. Comparative analysis thus reveals that categorical perception is not unique to humans, nor did it evolve for language.

More recent research has extended comparative study of the language faculty in two significant directions: the implementation of nontraining methods and the presentation of speech stimuli other than phonetic categories. In a series of studies comparing human neonates and adult cotton-top tamarins, results suggest that these species share a perceptual mechanism for discriminating the rhythmic classes of spoken languages (for recent results and detailed references see Tincoff *et al.*, 2005). Early descriptions of language rhythms separated them into three major classes reflecting linguistic metrical timing units: stress patterns, syllable length, and a subsyllabic unit length termed the mora. More recently, a quantitative analysis has been conducted of the acoustic characteristics of consonant and vowel units in several spoken languages. This analysis largely confirmed the early descriptive categories and revealed rhythmic clusters such as English and Dutch (stress timed), Spanish and Italian (syllable timed), and Japanese (mora timed). Perceptual experiments with human adults and newborns further confirmed this rhythmic organization. Most recently, human newborns and cotton-top tamarin species were tested in a habituation–discrimination paradigm using the same set of human speech utterances drawn from languages with different rhythmic structures (e.g., stress-timed Dutch vs. mora-timed Japanese). The discrimination response of human newborns was assessed with a high-amplitude sucking measure that capitalized on newborns' natural sucking reflex. The discrimination response of adult tamarin monkeys was assessed by a head orientation measure that capitalized on tamarins' spontaneous tendency to orient to a sound source. Results from both species showed that following habituation to one language (e.g., Dutch), individuals responded more to new sentences from a different rhythmic-class language (e.g., Japanese) than they did to new sentences from the habituation language. Both subject groups, however, failed to discriminate within a rhythmic class (e.g., Dutch vs. English or Spanish vs. Italian) and when the utterances were played backwards, a manipulation that arguably disrupts the rhythmic cues. Figure 1 presents the results of the tamarin subjects across these test conditions. The use of these natural spontaneous responses, compared to arbitrary trained responses, lends stronger support to the conclusion that the shared discrimination ability is based on a homologous perceptual mechanism.

Figure 1 Response to test utterances from New language compared to test utterances from Same, habituated language. Stippled bars indicate responses to different rhythmic class comparisons, Dutch vs. Japanese and Polish vs. Japanese. Solid bars indicate responses to same rhythmic class comparison, Dutch vs. American English. The top panel presents responses to utterances played forward; the bottom panel presents responses to utterances played backwards. Adult tamarins responded significantly more to New language utterances than to Same language utterances when the utterances were played forward and were from different rhythmic classes (*$p < 0.05$). Tamarins failed to discriminate New language utterances when they were played backwards, and when played forward, but were from the same rhythmic class. ([a]percentage of subjects responding, [b]mean percentage of responses across subjects).

Another perceptual domain that extends our knowledge of the sensory-motor system is cross-modal integration. Natural spoken language in face-to-face interactions is both an auditory and a visual/articulatory signal. Much research has documented that humans integrate the acoustic and articulatory sources of spoken syllables into a single percept. Research testing human infants' perception of multimodal stimuli such as sound–object matches, face–voice matches, and auditory-visual vowels shows that cross-modal integration is present from a young age (for reviews see chapters in Lewkowicz and Lickliter, 1994). Experiments with nonhuman subjects, especially primates, are critical for explaining the origins of this fundamental perceptual mechanism and identifying possible homologues or precursors. Recently, a laboratory experiment revealed that rhesus monkeys can spontaneously match the auditory signal of two of their natural vocalizations with the video of the appropriate articulatory gesture: coos, produced by a rhesus monkey caller with a small mouth opening and protruding

lips, and aggressive threats, produced with a larger mouth opening and no lip protrusion (Ghazanfar and Logothetis, 2003). This finding provides the first evidence that the perceptual mechanism for cross-modal matching of acoustic-articulatory cues may be homologous between humans and primates and inherited from a common primate ancestor. It remains an open question whether this mechanism can be used by animals to detect cross-modal matches and mismatches with speech and human faces, and similarly, whether humans could detect correspondences between rhesus faces and voices.

The above findings provide support for the conclusion that at least three perceptual mechanisms utilized by the sensory-motor system of the language faculty evolved before humans, and are homologous with mechanisms present in nonhuman primates and, in the case of categorical perception, other vertebrates. Importantly, these mechanisms evolved to solve more general perceptual problems rather than those that humans specifically encounter in processing speech. These findings are consistent with the first part of the language evolution hypothesis in Hauser *et al.* (2002), emphasizing commonalities within FLB.

Evidence of Phylogenetically Unique Mechanisms

The conceptual-intentional system includes conceptual representations (e.g., number, animacy, color, spatial referents), the capacity to attribute mental states (e.g., beliefs, desires, intentions), and the ability to form and extend a lexicon of words or word-like signals. A long history of comparative research has led to the general conclusion that nonhuman animals, and perhaps especially chimpanzees, have a rich conceptual system, including elements of a theory of mind (see chapters in Heyes and Huber, 2000; Bekoff *et al.*, 2002; Tomasello *et al.*, 2003). These animals lack, however, the full-blown systems observed in humans, and certainly lack the capacity to express in sounds or gestures what they are thinking about (Hauser *et al.*, 2002). Here we focus further on the lexical aspects of the conceptual-intentional system, as they reveal striking differences.

The classic studies of vervet monkeys show that they produce acoustically distinct behavioral and vocal responses to different predator classes (leopards, eagles, and snakes) (reviewed in Hauser, 1996; Cheney and Seyfarth, in press). In particular, field playback experiments demonstrated that vervets could infer the context from the call alone. These findings motivated the conclusion that animals might produce signals that function like symbols, labeling particular external referents or designating instructions for action. A strong claim building on this conclusion proposes that signals such as vervet alarm calls are evidence of precursors to human words. A more cautious claim allows that these signals carry significant information that can be decoded by the listener in order to mediate adaptive responses in the context of food, predation, and social relationships, but that information is not intentionally encoded by the sender to accommodate the listener's beliefs or desires (Cheney and Seyfarth, in press). We, along with most in the field, consider this latter interpretation to be correct. Additionally, nonhuman vocalizations differ from human words in at least three important ways: meaning, as reflected by acoustically distinct calls produced in particular situations, is tied to a narrow range of topics, survival and mating; the calls are never produced in the absence of the referent; and the lexicon is small and finite with no apparent capacity to generate novel sounds with new meaning (Hauser *et al.*, 2002). The implication for the evolution of the language faculty is that our lexical capacity likely stands as a phylogenetically novel trait; if correct, then models and simulations of language evolution that begin with the capacity for reference have skipped over a fundamental evolutionary change. We therefore need a better understanding of when and how our species alone acquired the remarkable capacity to learn words as young children, to generate new words on the fly, and to use our words to refer to absent, or even nonexistent and imagined, entities or events.

FLN – and especially the mechanism of recursion – was defined by Hauser *et al.* (2002)as a computational process that is responsible for the generative and hierarchical properties of narrow syntax. In discussing this system, they leave open the possibility that although the recursive machinery is essential to language, it is also deployed, at least in some form, in other domains. On this view, therefore, a much broader array of investigations is likely to be useful to our understanding of language evolution. For example, comparative studies have explored the generative or hierarchical mechanisms for number and serial-order learning (Biro and Matsuzawa, 2001; Terrace *et al.*, 2003), tool use (Matsuzawa, 2001), foraging and navigation (Shettleworth, 1998), and human grammar (Fitch and Hauser, 2004; Newport *et al.*, 2004). We focus here on studies testing primates' processing of grammar as they provide the most direct test of the FLN system used for narrow syntax. These laboratory studies build on the perceptual studies reviewed above using a familiarization–discrimination test paradigm with natural or synthesized speech stimuli and the same spontaneous orienting measure. The findings show that cotton-toptamarin monkeys share with humans the basic

Figure 2 Mean response across subjects to test patterns that violated familiarized grammar compared to test patterns consistent with grammar. The top panel shows that tamarins familiarized to the finite state grammar (FSG) responded significantly more to violations than to grammar consistent patterns, but tamarins familiarized to the phrase structure grammar (PSG) did not discriminate violations from consistent patterns.

computational mechanisms for calculating transitional probabilities (a cue to word boundaries) and extracting algebraic rules (AAB vs. ABB), as well as other finite-state grammars (AB^n patterns). Unlike humans, however, tamarins fail to extract phrase structure grammars (A^nB^n patterns) (Fitch and Hauser, 2004). In this experiment, tamarins were first familiarized to sets of syllables following an A^nB^n grammar. They were then tested with novel items, half violating the grammar, half consistent with it. Tamarins responded equally to the test items, failing to discriminate violations from grammar-consistent items (see Figure 2). This failure cannot be explained by task demands (identical to those used in the finite-state grammar experiment), working memory, capacity to extract the relevant units for the computation (i.e., the syllables were previously used in experiments testing finite-state grammar and algebraic rules), or number. These results suggest that the mechanism for generating hierarchically embedded structures is a phylogenetically novel trait unique to humans.

Conclusions and Open Questions

Although comparative studies related to the language faculty have a long history, most of the core issues associated with understanding the evolution of the language faculty have only recently been approached. One useful approach may be the theoretical framework articulated by Hauser *et al.* (2002) in which the language faculty is carved at several relevant joints, including at the simplest level, the broad and narrow sense with the associated component systems and its interfaces. Comparative studies with nonhuman primates and other animals offer initial support that the sensory-motor component of FLB is homologous. In contrast, the available data suggest that the conceptual-intentional system of FLB is characterized by a pattern of homologous, homoplasic, and phylogenetically unique traits. Finally, no strong evidence has been gathered to argue for a nonhuman homologue or homoplasy for FLN; FLN, as defined for narrow syntax, is a strong candidate for a phylogenetically unique human trait within the language faculty.

Despite these positive developments, the conclusions presently rest on a sparse foundation due to the paucity of species tested and the range of unrelated methods implemented. Furthermore, important caveats must be raised for the identified behavioral homologies. We know relatively little about the neurophysiological substrates for any of the behavioral phenomena described, or the genetic mechanisms that form these processes. Further probing could reveal that the similar behavioral responses are generated by phylogenetically different underlying systems that yield convergent behavior. Alternatively, further probing could reveal homologies throughout the relevant neural, hormonal, or genetic mechanisms. An additional question is whether the target mechanisms serve an adaptive function related to language or if they are byproducts of other adaptations that were co-opted by the language faculty. Studies using neurophysiological preparations with natural vocalizations and human speech, together with studies involving molecular techniques, provide important avenues for the future (for a perspective on the recent mapping of the FOXP2 complex see Marcus and Fischer, 2003). The study of language evolution is an exciting and growing area of linguistics and language behavior. Data from nonhuman animals will play a pivotal role in constraining theories and designing experiments.

Cognitive Grammar

R W Langacker

This article is reproduced from the previous edition, volume 2, pp. 590–593, © 1994, Elsevier Ltd.

'Cognitive grammar' (originally called 'space grammar') is a highly innovative theory of linguistic structure that has been developed and progressively articulated since 1976. In stark contrast to modular approaches, it regards language as an integral facet of cognition, and grammar as being inherently meaningful. It presupposes a 'conceptualist' account of linguistic semantics that properly recognizes our capacity for construing the same conceived situation in alternate ways. With an appropriate view of meaning, all grammatical elements are reasonably attributed some kind of conceptual import. Grammar is thus considered 'symbolic' in nature: it reduces to the structuring and symbolization of conceptual content.

Linguistic Organization

The ultimate goal of linguistic research is to characterize language as a cognitive entity. As envisaged in cognitive grammar, linguistic structure ultimately

reduces to recurrent patterns of neurological activity, and owing to its multifaceted complexity, a language is more aptly likened metaphorically to a biological organism than to a computer program or a logical deductive system. Thus it is not presumed that any single formalism can capture all aspects of a given phenomenon, or that any particular notation translates directly into specific psychological claims. The various notations and descriptive formats devised in cognitive grammar are meant to be precise within the limits of our understanding and revelatory for particular descriptive and analytical purposes. They do not however constitute a strict or uniquely privileged formalization, nor is the expectation of such a formalism considered appropriate.

To the extent that a pattern of neurological activity is 'entrenched' and readily elicited as a pre-established whole, it is referred to as a 'unit.' Linguistic knowledge or ability (i.e., a speaker's grasp of linguistic convention) comprises a vast array of such units, which is structured in the sense that units participate in excitatory and inhibitory relationships, and that some units include others as components. This knowledge – the 'internal grammar' – is not conceived as a generative or constructive device. The function of linguistic units is rather to serve as templates for the 'categorization' of expressions. An expression is simultaneously categorized by a multitude of units, each of which corresponds to a particular aspect of its structure and represents a constraint on its possible well-formedness (conventionality). Units compete for activation and the privilege of categorization on the basis of entrenchment and their degree of overlap with the target expression.

Cognitive grammar imposes severe limitations on the kinds of units ascribable to a linguistic system. On the one hand, it posits only (a) semantic units, (b) phonological units, and (c) symbolic units (in which semantic and phonological units are linked by symbolic relationships). This is the bare minimum needed to accommodate the basic semiological function of language, namely the symbolization of conceptualizations by means of phonological sequences. Symbolic units are held sufficient for the description of lexicon, morphology, and syntax, which form a continuum (rather than discrete components). On the other hand, cognitive grammar observes the 'content requirement,' which restricts linguistic units to (a) semantic, phonological, and symbolic structures that occur overtly as (parts of) expressions, (b) 'schematizations' of permitted structures, and (c) 'categorizing relationships' between permitted structures (including 'instantiation' of a schema and 'extension' from a prototype). By virtue of these restrictions, the theory achieves naturalness, conceptual unification, and theoretical austerity.

Semantic Structure

Cognitive grammar maintains that grammatical structure is 'symbolic' in nature, being fully describable in terms of symbolic links between semantic and phonological structures. The viability of this conception of grammar depends on a particular view of linguistic semantics.

Basic Tenets

Cognitive semantics rests on several fundamental notions. First, meaning is not identified with truth conditions, but with 'mental experience' or 'conceptualization' in the broadest sense of that term. Included are novel conceptions (as well as established concepts), all facets of sensorimotor experience, and cognizance of the social, linguistic, and cultural context. Second, a linguistic category is typically 'complex': its adequate description requires not just a single structure, but a set of structures linked by relationships of instantiation and extension to form a network. As a special case of this phenomenon, lexical items are typically 'polysemous.' A lexeme's meaning comprises a network of related senses, some being schematic relative to others, and some constituting extensions vis-à-vis more prototypical values. Third, linguistic semantics is 'encyclopedic' in scope. The meaning of a lexical item (even a single sense) cannot in general be captured by a limited, dictionary-type definition. Everything we know about an entity can in principle be regarded as contributing to the meaning of an expression that designates it, even though certain specifications are far more central and linguistically important than others. One cannot motivate any sharp distinction (only one of degree) between semantics and pragmatics, or between 'linguistic' and 'extralinguistic' knowledge. Finally, an expression's meaning does not consist solely in the conceptual content it evokes (let alone in truth conditions or the objective situation it describes) – equally significant is how that content is 'construed.' Two expressions may invoke the same conceptual content yet differ semantically by virtue of the construals they impose.

Construal

Numerous aspects of construal have been identified. They are conveniently grouped under several broad rubrics: specificity, scope, background, perspective, and prominence.

We have the capacity to conceive an entity or situation at varying levels of specificity and detail, as witnessed by such hierarchies as *thing* > *creature* > *insect* > *fly* > *fruit fly*. Each term in the hierarchy is 'schematic' for (and 'elaborated' by) the one that

follows, which characterizes the designated entity with greater precision (finer resolution).

An expression's 'scope' comprises the full array of conceptual content that it specifically evokes and relies upon for its characterization. The term 'lid,' for instance, evokes the schematic conception of a container, as well as the notion of one entity covering another. A conception of any type or any degree of complexity is capable of being invoked as part of an expression's meaning. Numerous conceptions – called 'cognitive domains' – typically figure in the meaning of a given expression, which may evoke them in a flexible and open-ended manner (as determined by context). Hence the starting point for semantic description is not a set of semantic features or conceptual primitives, but rather an appropriate array of integrated conceptions, among them higher-order structures representing any level of conceptual organization. At the lowest level, presumably, are cognitively irreducible 'basic domains' such as space, time, and the domains associated with the various senses (e.g., color space).

Another aspect of construal is our ability to conceive of one structure against the 'background' provided by another. Categorization is perhaps the most fundamental and pervasive manifestation of this ability. Another is the relationship between the source and target domains of a metaphor. Words like *even, only, many, few, more*, and *less* compare an actual value to some norm or expectation, and the contrast between the truth-functionally equivalent *half-empty* and *half-full* is well known. More generally, such phenomena as presupposition, anaphora, and the given/-new distinction all involve construal against a certain kind of background.

Perspective subsumes such factors as *vantage point, orientation*, and the *subjectivity* or *objectivity* with which an entity is construed. Vantage point and orientation both figure in the two interpretations of *Jack is to the left of Jill*, where Jack's position may be reckoned from either the speaker's perspective or from Jill's. By subjectivity or objectivity is meant the degree to which an entity functions asymmetrically as the 'subject' or the 'object of conception.' The conceptualizers (i.e., the speaker and addressee) are construed subjectively in *There's a mailbox across the street*, where they remain implicit as 'offstage' reference points. They construe themselves more objectively in *There's a mailbox across the street from us*.

The final aspect of construal is the relative 'prominence' accorded to the different substructures of a conception. Various kinds of prominence need to be distinguished. One is the salience that comes with objective construal and explicit mention, as in the previous example. A second type of prominence is called 'profiling': within the conception it evokes, every expression singles out some substructure as a kind of focus of attention; this substructure – the 'profile' – is the one that the expression 'designates.' For example, *hypotenuse* evokes the conception of a rightangled triangle (its scope) and profiles (designates) the side lying opposite the right angle. *Above* profiles the spatial 'relationship' between two entities. A third type of prominence pertains to the participants in a profiled relationship. One participant, termed the 'trajector,' is analyzed as the 'figure' within the profiled relationship; an additional salient entity is referred to as a 'landmark.' For instance, because *above* and *below* evoke the same conceptual content and profile the same relationship, their semantic contrast can only reside in figure/ground alignment. *X is above Y* is concerned with locating *X*, which is thus the trajector (relational figure), whereas *Y is below X* uses *X* as a landmark to specify the location of *Y*.

Grammatical Structure

Grammar is claimed to be 'symbolic' in nature. Only symbolic units (form-meaning pairings) are held necessary for the description of grammatical structure. Thus all valid grammatical constructs are attributed some kind of conceptual import. Rather than being autonomous in regard to semantics, grammar reduces to the structuring and symbolization of conceptual content.

Grammatical Classes

An expression's grammatical class is determined by the nature of its profile. The most fundamental distinction is between a 'nominal' and a 'relational' expression, which respectively profile a 'thing' and a 'relationship.' Both terms are defined abstractly. A thing is characterized schematically as a 'region in some domain,' where a 'region' can be established from any set of entities (e.g., the stars in a *constellation*) just by conceiving of them in relation to one another. While physical objects occupy bounded regions in space and are prototypical instances of the thing category, the schematic characterization also accommodates such entities as as unbounded substances (e.g., *water*), geographical areas (*Wisconsin*), regions in abstract domains (*stanza*), collections of entities (*alphabet*), points on a scale (*F-sharp; 30°C*), conceptual reifications (*termination*), and even the absence of some entity (*intermission*). The term 'relationship' is also broadly interpreted. It applies to any assessment of entities in relation to one another, regardless of their nature and status; in particular, they need not be distinct, salient, or individually recognized. Expressions classified as relational are

therefore not limited to those (like *above*) traditionally considered two-place predicates. For instance, the adjective *blue* profiles the relationship between an object and a certain region in color space. When used as a noun, *square* profiles the region comprising a set of line segments arranged in a particular fashion (or else the area they enclose). When used as an adjective, however, it profiles the complex relationship among subparts of this geometrical figure (involving perpendicularity, equal length of sides, and so on).

Expressions that profile things include such traditional classes as noun, pronoun, and noun phrase (for which the term 'nominal' is adopted in cognitive grammar). Relational expressions subsume those traditionally recognized as adjectives, prepositions, adverbs, infinitives, participles, verbs, clauses, and full sentences. On the basis of the intrinsic complexity of their profiles, relational expressions can be divided into those which designate 'simple atemporal relations,' 'complex atemporal relations,' and 'processes.' A simple atemporal relation is one that comprises a single consistent configuration (or 'state' – hence it is also called a 'stative relation'). For example, adjectives and many prepositions have this character. A complex atemporal relation cannot be reduced to a single configuration but can only be represented as an ordered series of states. In *She walked across the field*, for instance, the preposition *across* designates a series of locative configurations defining the trajector's path with reference to the landmark. A process is a complex 'temporal' relation, i.e., one whose component states are saliently conceived as being distributed through a continuous span of time, and whose temporal evolution is viewed sequentially (rather than holistically). Verbs and finite clauses designate processes, whereas participles and infinitives impose a holistic view on the process specified by a verb stem and are thus atemporal.

Rules and Constructions

Grammar consists of patterns for combining simpler symbolic structures into symbolic structures of progressively greater complexity. A symbolically complex expression, e.g., *cracked*, represents a 'grammatical construction' wherein two 'component structures' (*crack* and *-ed*) are 'integrated' to form a 'composite structure.' Such integration, both phonological and semantic, is effected by 'correspondences' established between subparts of the component expressions, and by the superimposition of corresponding entities. Typically, one component structure corresponds to, and serves to 'elaborate,' a schematic substructure within the other. Thus *-ed*, being a suffix, makes schematic phonological reference to a stem, which *crack* elaborates to yield *cracked*. Semantically, the adjectival sense of the past participial morpheme profiles the final, resultant state of a schematically characterized process, which corresponds to the specific process profiled by *crack*. By superimposing the corresponding processes, and adopting the profiling of the participial morpheme, one obtains the composite semantic structure of *cracked*, which profiles a stative relation identified as the final state of *crack*.

It is usual for the composite structure to inherit its profiling from one of the component structures, which thereby constitutes the construction's 'head.' The suffix *-ed* is thus the head within the participial construction *cracked*. A component that elaborates the head is a 'complement,' hence complement of *-ed* by virtue of elaborating the schematic process it invokes. Conversely, a component that the head elaborates is a 'modifier.' In *blue square*, for instance, *blue* modifies *square* because the latter – the head – elaborates *blue*'s schematic trajector (the entity located in the blue region of color space).

Grammatical rules take the form of schematized constructions. A 'constructional schema' is a symbolically complex structure whose internal organization is exactly analogous to that of a set of constructions (complex expressions), but which abstracts away from their points of divergence to reveal their schematic commonality. For instance, the rule for adjective + noun combinations in English is a symbolic structure parallel to *blue square, cracked sidewalk, playful kitten*, etc., except that the adjective and noun are schematic rather than specific: semantically, the constructional schema specifies that the trajector of the adjective corresponds to the profile of the noun, which lends its profile to the composite structure; phonologically, it specifies that the adjective directly precedes the noun as a separate word. A constructional schema may be characterized at any appropriate level of abstraction, and represents the conventionality of a particular pattern of integration. It is available for the categorization of novel complex expressions and can also be thought of as a template used in their assembly.

Other Grammatical Elements

The foregoing remarks indicate that grammatical classes, rules, and such notions as head, complement, and modifier can all be characterized in terms of configurations of symbolic structures. The same is true of other grammatical elements. For instance, a 'nominal' (noun phrase) profiles a thing and further incorporates a specification of its relationship to the 'ground' (i.e., the speech event and its participants) with respect to fundamental, 'epistemic' cognitive domains; demonstratives, articles, and certain quantifiers serve this function in English. Similarly, a

'finite clause' profiles a process grounded (in the case of English) by tense and the modals. A 'subject' can then be characterized as a nominal which elaborates the trajector of a process profiled at the clausal level of organization, and a 'direct object' as a nominal that elaborates its primary landmark.

Grammatical markers are all attributed semantic values, often quite schematic. For example, the derivational morpheme *-er* (as in *complainer*) profiles a thing characterized only as the trajector of a schematic process; like most derivational morphemes, it is semantically schematic for the class it derives, its primary semantic value residing in the profile it imposes on the specific conceptual content provided by the stem it combines with. Besides schematicity, factors considered compatible with a grammatical marker's meaningfulness include semantic overlap with other elements (e.g., redundant marking, as in agreement), the lack of any option (as in government), and failure to exhibit a single sense in all its uses (polysemy being characteristic of both lexical and grammatical elements – e.g., *-ed* has distinct but related meanings in its adjectival, perfect, and passive uses).

Assessment and Outlook

Cognitive grammar has been revealingly applied to a steadily widening array of phenomena in a diverse set of languages. It is rapidly being established as a viable model of language structure, and in view of the restrictiveness and conceptual unification it achieves, it merits serious attention from linguistic theorists. It is fully compatible with 'functional' approaches to linguistic structure, which help explain why certain of the structures it permits have the status of prototypes, or represent language universals or universal tendencies. It also has a natural affinity to 'connectionist' (or 'parallel distributed processing') models of cognition, both because the distinction between rules and data is only one of degree, and also because grammatical structure reduces to form–meaning pairings. The possibility of achieving this reduction has extensive implications for language acquisition, models of language processing, and our conception of the human mind.

Cognitive Linguistics

L Talmy, State University of New York, Buffalo, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Developing over the past two to three decades, cognitive linguistics has as its central concern the representation of conceptual structure in language. This relatively new field can initially be characterized through a contrast of its conceptual approach with two other familiar approaches, the formal and the psychological. The formal approach focuses on the overt structural patterns exhibited by linguistic forms, largely abstracted away from any associated meaning. The tradition of generative grammar has been centered here, but has had limited involvement with the other two approaches. Its formal semantics has largely included only enough about meaning to correlate with its formal categories and operations. And its reach to psychology has largely considered only the kinds of cognitive structure and processing needed to account for its formal categories and operations. The psychological approach regards language from the perspective of general cognitive systems such

'finite clause' profiles a process grounded (in the case of English) by tense and the modals. A 'subject' can then be characterized as a nominal which elaborates the trajector of a process profiled at the clausal level of organization, and a 'direct object' as a nominal that elaborates its primary landmark.

Grammatical markers are all attributed semantic values, often quite schematic. For example, the derivational morpheme *-er* (as in *complainer*) profiles a thing characterized only as the trajector of a schematic process; like most derivational morphemes, it is semantically schematic for the class it derives, its primary semantic value residing in the profile it imposes on the specific conceptual content provided by the stem it combines with. Besides schematicity, factors considered compatible with a grammatical marker's meaningfulness include semantic overlap with other elements (e.g., redundant marking, as in agreement), the lack of any option (as in government), and failure to exhibit a single sense in all its uses (polysemy being characteristic of both lexical and grammatical elements – e.g., *-ed* has distinct but related meanings in its adjectival, perfect, and passive uses).

Assessment and Outlook

Cognitive grammar has been revealingly applied to a steadily widening array of phenomena in a diverse set of languages. It is rapidly being established as a viable model of language structure, and in view of the restrictiveness and conceptual unification it achieves, it merits serious attention from linguistic theorists. It is fully compatible with 'functional' approaches to linguistic structure, which help explain why certain of the structures it permits have the status of prototypes, or represent language universals or universal tendencies. It also has a natural affinity to 'connectionist' (or 'parallel distributed processing') models of cognition, both because the distinction between rules and data is only one of degree, and also because grammatical structure reduces to form–meaning pairings. The possibility of achieving this reduction has extensive implications for language acquisition, models of language processing, and our conception of the human mind.

Cognitive Linguistics

L Talmy, State University of New York, Buffalo, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

Developing over the past two to three decades, cognitive linguistics has as its central concern the representation of conceptual structure in language. This relatively new field can initially be characterized through a contrast of its conceptual approach with two other familiar approaches, the formal and the psychological. The formal approach focuses on the overt structural patterns exhibited by linguistic forms, largely abstracted away from any associated meaning. The tradition of generative grammar has been centered here, but has had limited involvement with the other two approaches. Its formal semantics has largely included only enough about meaning to correlate with its formal categories and operations. And its reach to psychology has largely considered only the kinds of cognitive structure and processing needed to account for its formal categories and operations. The psychological approach regards language from the perspective of general cognitive systems such

as perception, memory, attention, and reasoning. Centered here, the field of psychology has also addressed the other two approaches. Its conceptual concerns have included semantic memory, the associativity of concepts, the structure of categories, inference generation, and contextual knowledge. But it has insufficiently considered systematic conceptual structuring.

By contrast, the conceptual approach of cognitive linguistics is concerned with the patterns in which and processes by which conceptual content is organized in language. It has thus addressed the linguistic structuring of such basic conceptual categories as space and time, scenes and events, entities and processes, motion and location, and force and causation. To these it adds the basic ideational and affective categories attributed to cognitive agents, such as attention and perspective, volition and intention, and expectation and affect. It addresses the semantic structure of morphological and lexical forms, as well as of syntactic patterns. And it addresses the interrelationships of conceptual structures, such as those in metaphoric mapping (*see* **Metaphor: Psychological Aspects**), those within a semantic frame, those between text and context, and those in the grouping of conceptual categories into large structuring systems. Overall, the aim of cognitive linguistics is to ascertain the global integrated system of conceptual structuring in language. Further, cognitive linguistics addresses the formal properties of language, accounting for grammatical structure in terms of its representation of conceptual structure. And, distinguishing it from earlier semantics, cognitive linguistics relates its findings to the cognitive structures of the psychological approach (*see* **Psycholinguistics: Overview**). Its long-range trajectory is to integrate the linguistic and the psychological perspectives on cognitive organization in a unified understanding of human conceptual structure.

Many of the major themes of cognitive linguistics can be related in a way that shows the overall structure of the field. A beginning observation is that language consists of two subsystems – the open-class or lexical, and the closed-class or grammatical – that have different semantic and functional properties. Closed-class, but not open-class forms, exhibit great semantic constraint, and do so at two levels. First, their referents can belong to certain semantic categories, such as number, gender, and tense, but not to others such as color or material. For example, inflections on a noun indicate its number in many languages, but never its color. Second, they can refer only to certain concepts even within an acceptable category like number – e.g., 'singular,' 'dual,' 'plural,' and 'paucal,' but never 'even,' 'odd,' or 'dozen.' Certain principles govern this semantic constraint, e.g., the exclusion of reference to Euclidean properties such as specificity of magnitude or shape. What largely remain are topological properties such as the magnitude-neutral distance represented by the deictics (*see* **Deixis and Anaphora: Pragmatic Approaches**) in *This speck/planet is smaller than that speck/planet*, or the shape-neutral path represented by the preposition in *I circled/zigzagged through the forest*. The two subsystems differ also in their basic functions, with conceptual content represented by open-class forms and conceptual structure by closed-class forms. For example, in the overall conception evoked by the sentence *A rustler lassoed the steers*, the three semantically rich open-class forms – *rustle, lasso, steer* – contribute most of the content, while most of the structure is determined by the remaining closed-class forms. Shifts in all the closed-class forms – as in *Will the lassoers rustle a steer?* – restructure the conception but leave the cowboy-landscape content largely intact, whereas a shift in the open-class forms – as in *A machine stamped the envelopes* – changes content while leaving the structure intact. The basic finding in this "semantics of grammar" portion of cognitive linguistics is that the closed-class subsystem is the fundamental conceptual structuring system of language (Talmy, 2000).

Such conceptual structure is understood in cognitive linguistics as 'schematic', with particular 'schemas' or 'image-schemas' represented in individual linguistic forms – whether alone in closed-class forms or with additional material in open-class forms. The idea is that the structural specifications of linguistic forms are regularly conceptualized in terms of abstracted, idealized, and sometimes virtually geometric delineations. Such schemas fall into conceptual categories that join in extensive 'schematic systems.' Many of the substantive findings about conceptual organization made by cognitive linguists can be placed within these schematic systems. One schematic system is 'configurational structure,' covering the structure of objects in space and events in time – often with parallels between the two. For example, inits category of 'plexity' – a term covering both number and aspect – the object referent of *bird* and the event referent of *(to) sigh* are intrinsically 'uniplex', but the addition of the extra forms in *birds* and *keep sighing* triggers a cognitive operation of 'multiplexing' that yields multiplex referents. And in the category 'state of boundedness,' the intrinsically unbounded object and event referents of *water* and *(to) sleep* can undergo 'bounding' through the additional form in *some water* and *(to) sleep some* to yield bounded referents.

The second schematic system of 'perspective' covers the location or path of the point at which one

places one's 'mental eyes' to regard a represented scene. For example, in *There are some houses in the valley*, the closed-class forms together represent a distal stationary perspective point with global scope of attention. But the substituted forms in *There is a house every now and then through the valley* represent a proximal moving perspective point with local scope of attention.

The third schematic system of 'attention' covers the patterns in which different aspects of a linguistic reference are foregrounded or backgrounded. For example, the word *hypotenuse* 'profiles' – foregrounds in attention – its direct reference to a line segment against an attentionally backgrounded 'base' of the conception of a right triangle (Langacker, 1987). The verb *bite* in *The dog bit the cat* foregrounds the 'active zone' of the dog's teeth. And over an expression of a certain kind, the 'Figure' or 'trajector' is the most salient constituent whose path or site is characterized in terms of a secondarily salient constituent, the 'Ground' or 'landmark.' These functional assignments accord with convention in *The bike is near the house*, but their reversal yields the odd *?The house is near the bike*.

A fourth schematic system of 'force dynamics' covers such relations between entities as opposition, resistance, overcoming, and blockage, and places causation alongside permitting and preventing, helping and hindering. To illustrate, the sentence *The ball rolled along the green* is force dynamically neutral, but in *The ball kept rolling along the green*, either the ball's tendency toward rest is overcome by something like the wind, or its tendency toward motion overcomes something such as stiff grass (Talmy, 2000).

Schemas from all the schematic systems, and the cognitive operations they trigger can be nested to form intricate structural patterns. To illustrate with events in time, the uniplex event in *The beacon flashed* can be multiplexed as in *The beacon kept flashing*; this can be bounded as in *The beacon flashed 5 times in a row*; this can be treated as a new uniplexity and remultiplexed as in *The beacon kept flashing 5 times at a stretch*; and this can in turn be rebounded, as in *The beacon flashed 5 times at a stretch for 3 hours*.

Further conceptual structuring is seen within the meanings of morphemes. A morpheme's meaning is generally a prototype category whose members differ in privilege, whose properties can vary in number and strength, and whose boundary can vary in scope (Lakoff, 1987). For example, the meaning of *breakfast* prototypically refers to eating certain foods in the morning, but can extend to other foods at that time or the same foods at other times (Fillmore, 1982). For a polysemous morpheme, one sense can function as the prototype to which the other senses are progressively linked by conceptual increments within a 'radial category.' Thus, for the preposition *over*, the prototype sense may be 'horizontal motion above an object' as in *The bird flew over the hill*, but linked to this by 'endpoint focus' is the sense in *Sam lives over the hill* (Brugmann, 1981).

These findings have led cognitive linguists to certain stances on the properties of conceptualization. The conceptual structuring found in language is largely held to be a product of human cognition and imposed on external phenomena (where it pertains to them), rather than arising from putative structure intrinsic to such external phenomena and veridically taken up by language. For example, in one type of 'fictive motion,' motion can be imputed to a shadow – cross linguistically always from an object to its silhouette – as in *The pole threw its shadow on the wall*, even though a distinct evaluative part of our cognition may judge the situation to lack physical motion. An important consequence is that alternatives of conceptualization or 'construal' can be applied to the same phenomena. Thus, a person standing 5 feet from and pointing to a bicycle can use either deictic in *Take away that/this bicycle*, in effect imputing the presence of a spatial boundary either between herself and the bicycle or on the far side of the bicycle.

The notion of 'embodiment' extends the idea of conceptual imposition and bases the imposed concepts largely on experiences humans have of their bodies interacting with environments or on psychological or neural structure (Lakoff and Johnson, 1999). As one tenet of this view, the 'objectivist' notion of the autonomous existence of logic and reason is replaced by experiential or cognitive structure. For example, our sense of the meaning of the word *angle* is not derived from some independent ideal mathematical realm, but is rather built up from our experience, e.g., from perceptions of a static forking branch, from moving two sticks until their ends touch, or from rotating one stick while its end touches that of another.

The cognitive process of conceptual imposition – more general than going from mental to external phenomena or from experiential to ideal realms – also covers directed mappings from any one conceptual domain to another. An extensive form of such imputation is metaphor, mainly studied in cognitive linguistics not for its familiar salient form in literature but, under the term 'conceptual metaphor,' for its largely unconscious pervasive structuring of everyday expression. In it, certain structural elements of a conceptual 'source domain' are mapped onto the content of a conceptual 'target domain.' The embodiment-based directionality of the imputational

mapping is from a more concrete domain, one grounded in bodily experience, to a more abstract domain – much as in the Piagetian theory of cognitive development. Thus, the more palpable domain of physical motion through space can be mapped onto the more abstract domain of progression through time – in fact, in two different ways – as in *We're approaching Christmas* and *Christmas is approaching* – whereas mappings in the reverse direction are minimal (Lakoff, 1992).

Generally, mappings between domains are implicit in metaphor, but are explicitly established by linguistic forms in the area of 'mental spaces.' The mapping here is again directional, going from a 'base' space – a conceptual domain generally factual for the speaker – to a subordinate space that can be counterfactual, representational, at a different time, etc. Elements in the former space connect to corresponding elements in the latter. Thus, in *Max thinks Harry's name is Joe*, the speaker's base space includes 'Max' and 'Harry' as elements; the word *thinks* sets up a subordinate space for a portion of Max's belief system; and this contains an element 'Joe' that corresponds to 'Harry' (Fauconnier, 1985). Further, two separate mental spaces can map elements of their content and structure into a third mental space that constitutes a 'blend' or 'conceptual integration' of the two inputs, with potentially novel structure. Thus, in referring to a modern catamaran reenacting a century-old voyage by an early clipper, a speaker can say *At this point, the catamaran is barely maintaining a 4 day lead over the clipper*, thereby conceptually superimposing the two treks and generating the apparency of a race (Fauconnier and Turner, 2002).

In terms of the sociology of the field, there is considerable consensus across cognitive linguists on the assumptions of the field and on the body of work basic to it. No competing schools of thought have arisen, and cognitive linguists engage in relatively little critiquing of each other's work, which mainly differs only in the phenomena focused on.

Cognitive Pragmatics

F M Bosco, University of Torino, Torino, Italy

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Cognitive pragmatics is concerned with the mental processes involved in intentional communication. Typically, studies within this area focus on cognitive processes underlying the comprehension of a linguistic speech act and overlook linguistic production or extralinguistic communication.

As far as cognitive processes are concerned authors in this field are interested in both the inferential chains necessary to understand a communicator's intention starting from the utterance he proffered and the different mental representations underlying the comprehension of various communicative phenomena as cognitive processes. Thus, a theory in cognitive pragmatics aims to explain what mental processes a person actually engages in during a communicative interaction (*see* **Shared Knowledge**).

Relevance theory (Sperber and Wilson, 1986/1995) is usually identified as the principal theoretical framework in the area of cognitive pragmatics (*see* **Relevance Theory**). Nonetheless, in the last decade, other theories have been developed. These include a far-reaching theory of the cognitive processes underlying human communication, known as the Cognitive Pragmatics theory (Airenti *et al.*, 1993a, 1993b; Bara, 2005), and the Graded Salience Hypothesis (Giora, 2003), a theory which focuses on mental inferences underlying the comprehension of literal vs. figurative language (*see* **Cognitive Linguistics**; **Metaphor: Psychological Aspects**).

Describing the cognitive processes involved in communicative interaction is interesting not only for the study of such processes as fixed states – an approach that takes into consideration exclusively the final stage in healthy adult subjects – but also for the consideration of how a given function develops from infancy, through childhood, and to adulthood, and how it eventually decays in subjects with brain injuries (Bara, 1995). Such an approach makes it possible to better comprehend, from a cognitive perspective, how pragmatic competence develops and what neurocognitive structures might cause deficits in people's performance if damaged.

A closely related topic is the identification of the cognitive components that contribute to the realization of a complete pragmatic competence. From this perspective, it is important to consider the role played by a person's Theory of Mind and by the Executive Function (see below) during a communicative interaction.

Cognitive Pragmatics Theory

Airenti *et al.* (1993a, 1993b) presented a theory of the cognitive processes underlying human communication aiming to provide a unified theoretical framework for the explanation of different communicative phenomena (Bara, 2005). The authors proposed that their theoretical analysis holds for both linguistic and extralinguistic communication, and thus introduced, with reference to the interlocutors, the terms 'actor' and 'partner' instead of the classical 'speaker' and 'hearer.' The theory assumes that the literal meaning of an utterance is necessary but not sufficient to the partner in order for him or her to reconstruct the meaning conveyed by the actor, and that in order to understand the actor's communicative intention, the partner has to recognize a 'behavior game' the actor is proposing for him (the partner) to play. The behavior game is a social structure mutually shared by the participants of the communicative interaction.

Introduction

Cognitive pragmatics is concerned with the mental processes involved in intentional communication. Typically, studies within this area focus on cognitive processes underlying the comprehension of a linguistic speech act and overlook linguistic production or extralinguistic communication.

As far as cognitive processes are concerned authors in this field are interested in both the inferential chains necessary to understand a communicator's intention starting from the utterance he proffered and the different mental representations underlying the comprehension of various communicative phenomena as cognitive processes. Thus, a theory in cognitive pragmatics aims to explain what mental processes a person actually engages in during a communicative interaction (*see* **Shared Knowledge**).

Relevance theory (Sperber and Wilson, 1986/1995) is usually identified as the principal theoretical framework in the area of cognitive pragmatics (*see* **Relevance Theory**). Nonetheless, in the last decade, other theories have been developed. These include a far-reaching theory of the cognitive processes underlying human communication, known as the Cognitive Pragmatics theory (Airenti *et al.*, 1993a, 1993b; Bara, 2005), and the Graded Salience Hypothesis (Giora, 2003), a theory which focuses on mental inferences underlying the comprehension of literal vs. figurative language (*see* **Cognitive Linguistics**; **Metaphor: Psychological Aspects**).

Describing the cognitive processes involved in communicative interaction is interesting not only for the study of such processes as fixed states – an approach that takes into consideration exclusively the final stage in healthy adult subjects – but also for the consideration of how a given function develops from infancy, through childhood, and to adulthood, and how it eventually decays in subjects with brain injuries (Bara, 1995). Such an approach makes it possible to better comprehend, from a cognitive perspective, how pragmatic competence develops and what neurocognitive structures might cause deficits in people's performance if damaged.

A closely related topic is the identification of the cognitive components that contribute to the realization of a complete pragmatic competence. From this perspective, it is important to consider the role played by a person's Theory of Mind and by the Executive Function (see below) during a communicative interaction.

Cognitive Pragmatics Theory

Airenti *et al.* (1993a, 1993b) presented a theory of the cognitive processes underlying human communication aiming to provide a unified theoretical framework for the explanation of different communicative phenomena (Bara, 2005). The authors proposed that their theoretical analysis holds for both linguistic and extralinguistic communication, and thus introduced, with reference to the interlocutors, the terms 'actor' and 'partner' instead of the classical 'speaker' and 'hearer.' The theory assumes that the literal meaning of an utterance is necessary but not sufficient to the partner in order for him or her to reconstruct the meaning conveyed by the actor, and that in order to understand the actor's communicative intention, the partner has to recognize a 'behavior game' the actor is proposing for him (the partner) to play. The behavior game is a social structure mutually shared by the participants of the communicative interaction.

Suppose, for example, that while you are working in your office, a colleague walks in and says: [1] *It's snowing outside*. Although the literal meaning of the utterance is completely clear, you probably are utterly bewildered about how to respond. Only if [1] is understood as an invitation not to go outside, a request to close the window, a proposal to go skiing next week-end (that is, only if, in some way, the reason or reasons for uttering the expression were evident), will you be able to make the necessary inferences and answer appropriately. The utterance, pure and simple, without a game to refer to, has in itself no communicative significance whatsoever. Thus, an utterance extrapolated from its context of reference has no communicative meaning and cannot have any communicative effect on the partner.

Starting from the assumption that the communicative meaning of an utterance is intrinsically linked to the context within which it is proffered, Bosco *et al.* (2004a) defined a taxonomy of six categories of context: Access, Space, Time, Discourse, Behavioral Move, and Status. Using contextual information, the partner can identify the behavior game bid by the speaker, which allows him to fully comprehend the actor communicative intention.

Following the tenets of the Cognitive Pragmatics theory, Bucciarelli *et al.* (2003) proposed that two cognitive factors affect comprehension of various kind of pragmatic phenomena: the 'inferential load' and the 'complexity of mental representations' underlying the comprehension of a communicative act.

Inferential Load: Simple and Complex Speech Acts

Searle (1975) claimed that in speech act comprehension, the literal interpretation of an utterance always has priority with respect to any other interpretations derived from it. According to Searle, understanding an indirect speech act, e.g., [2] *Would you mind passing me the salt?*, is harder than understanding a direct speech act, e.g., [3] *Please pass me the salt*, because it requires a longer inferential process.

Bara and Bucciarelli (1998) provided empirical evidence that, beginning at two-and-a-half years of age, children find direct speech acts such as [4] *Please sit down*, and conventional indirects such as [5] *Would you mind closing the door?* equally easy to comprehend. In a further study, Bucciarelli *et al.* (2003) found that starting at age two-and-a-half years, children find both direct and conventional indirect speech acts easier to understand than nonconventional indirect speech acts, such as the utterance [6] *Excuse me, I'm studying* when it is a request to a partner who is hammering in a nail to stop making noise.

Using the tenets of Cognitive Pragmatics theory, it is possible to abandon the distinction between direct and indirect speech acts and adopt a new one based on the difference between inferential processes involved in comprehending simple as against complex communicative acts (Bara and Bucciarelli, 1998). According to the theory, the partner's understanding of any kind of speech act depends on the comprehension of the behavioral game bid by the actor; an agent will interpret an interlocutor's utterance based on the grounds that are assumed to be shared. In this perspective, the partner's difficulty in understanding a communicative act depends on the inferential chain necessary to refer the utterance to the game intended by the actor. Direct and conventional indirect speech acts make immediate reference to the game, and thus are defined as 'simple speech acts.' On the other hand, nonconventional indirect speech acts can be referred to as 'complex speech acts,' because they require a chain of inferential steps due to the fact that the specific behavior game of which they are a move is not immediately identifiable. For example, to understand [4] and [5], it is sufficient for the partner to refer to the 'Ask for Something' game. In order to understand [6], a more complex inferential process is necessary: the partner needs to share with the actor the belief that when a person is studying, he needs silence and that since hammering [6] is a request to stop is noisy. Only then, the partner can attribute to the utterance the value of a move in the 'Ask for Something' game. Thus, if the problem is how to access the game, the distinction between direct and indirect speech acts is not relevant. It is the complexity of the inferential steps necessary to refer the utterance to the game bid by the actor that accounts for the difficulties in speech act comprehension.

This distinction applies not only to standard communicative acts such as direct, conventional indirect, and nonconventional indirect speech acts, but also to nonstandard ones such as ironic and deceitful (Bara *et al.*, 1999a). The same distinction between simple and complex standard, ironic, and deceitful communicative acts holds for extralinguistic communication acts as well (*see* **Irony**). That is, the distinction holds also when the actor communicates with the partner only through gestures (Bosco *et al.*, 2004b) (*see* **Gestures: Pragmatic Aspects**).

The inferential load underlying a communicative act may explain the difference in difficulty that exists in the comprehension of different communicative acts pertaining to the same pragmatic category, such as between simple and complex standard communicative acts. To explain the difference in difficulty that might occur among communicative acts pertaining to a different pragmatic category, such as between a

direct communicative act and a deceitful communicative act, is necessary to consider the complexity of the mental representations involved in their comprehension.

Complexity of Mental Representations

Still within the framework of Cognitive Pragmatics theory and along with the same complexity of the inferential load involved, Bucciarelli *et al.* (2003) described an increasing difficulty in comprehending simple communicative acts of different sorts: simple standard, simple deceitful, and simple ironic communicative acts.

According to the theory, in standard communication, default rules of inference are used to understand another person's mental states; default rules are always valid unless their consequences are explicitly denied. Indeed, in standard communication, what the actor says is in line with his private beliefs. Direct, conventional indirect, and nonconventional indirect speech acts are all examples of standard communication. In terms of mental representations, to comprehend a standard communicative act, the partner has to simply refer the utterance proffered by the actor to the behavior game he bids.

On the other hand, nonstandard communication such as irony and deceit involves the comprehension of communicative acts *via* the block of default rules and the occurrence of more complex inferential processes that involve conflicts between the beliefs the actor has shared with the partner and the latter's private beliefs. In the comprehension of irony and deceit, the mental representations involved produce a difference between what the actor communicates and what he privately entertains. It follows that, along with the same complexity of the inferential load involved, standard communicative acts are easier to deal with than nonstandard pragmatic phenomena.

According to Bucciarelli *et al.* (2003), in the case of the comprehension of deceit, the partner has to recognize the difference between the mental states that are expressed and those the actor privately entertains. Consider for instance the following example: Mark and Ann share that the lecture they just attended was incredibly boring. Later Ann meets John and tells him that Mark and she attended a tedious lecture. In the afternoon also Mark meets John, who asks him about the lecture. Actually, Mark is annoyed with John because John did not go to the lecture and he does not want John to know that he feels he wasted the whole morning. Mark does not know that John has already met Ann, thus he answers: [7] *It was really interesting!* John can understand that Mark is trying to deceive him because he recognizes the difference between the mental state that Mark is expressing and the one that he truly and privately entertains.

A statement, instead, becomes ironic when, in addition to the awareness of this difference, the partner also recognizes that the mental states expressed contrast with the scenario that he shares with the actor. For example, some months later, during a chat with Mark, Ann asks: *Do you remember the lecture that we attended some months ago?* Mark answers: [8] *It was really interesting!* What makes this utterance ironic is the fact that both interlocutors share that the lecture had actually been boring. Thus, the difference between irony and deceit lies not in the partner's awareness of the difference between the mental states that the actor expressed and those that he actually entertains, but in his awareness that he does or does not share this difference with the actor.

In the case of irony, the partner has to represent not only the discrepancy between the mental states that the actor expressed and those that he privately entertains, but also that such awareness is shared with the actor. This makes an ironic communicative act more difficult to comprehend than a deceitful one.

Bucciarelli *et al.* (2003) showed the existence of an increase in difficulty in the comprehension of simple standard communicative acts, simple deceits, and simple ironies with an experiment carried out on children from two-and-a-half to seven years of age. The authors also pointed out that the same children show a similar predicted gradation of difficulty in understanding the same pragmatic phenomena, both when these are expressed by linguistic speech acts and when these are expressed by communicative gestures. Regardless of the communicative channel used by the actor, linguistic or extralinguistic, children find simple standard speech acts easier to comprehend than simple deceits, which are, in turn, easier to comprehend than simple ironic communicative acts.

Finally, an overall consideration of the mentioned results makes it possible to conclude that all of the theoretical predictions (both derived from the Cognitive Pragmatics theory and grounded on a person's cognitive processes underlying the communicative comprehension) hold true for the same pragmatic phenomena whether expressed by linguistic speech acts or by gestures. These results seem to indicate that linguistic and extralinguistic communicative acts share the most relevant mental processes in each of the specific pragmatic phenomena investigated and suggest that pragmatic competence shares the same cognitive faculty – regardless of the input processed – be it linguistic or extralinguistic. It is possible to interpret such empirical evidence as being in favor of a unified theoretical framework of

human communication in which linguistic and extralinguistic communication develop in parallel being different aspects of a unique communicative competence (see Bara and Tirassa, 1999; Bara, 2005) (*see* **Communicative Principle and Communication**).

Cognitive Pragmatics and Development

In this section, we shall examine the empirical evidence in favor of the existence of cognitive processes of increasing complexity that underlie different pragmatic phenomena. The developmental domain is particularly interesting for this aim because it makes it possible to observe errors in the comprehension of different kinds of pragmatics tasks that allow us to falsify our hypotheses regarding the complexity of the mental processes involved in specific phenomena. However, adult subjects possess a fully developed cognitive system and communicative competence, and thus they do not show any interesting errors in comprehending or producing different kinds of communicative acts; it is only possible to analyze their time of reaction in solving such tasks.

On the other hand, if inferential processes and mental representations of increasing complexity underlie the comprehension of various kind of pragmatic phenomena, then it is possible to explain why, during the development of children's communicative competence, some communicative acts are understood and produced before others are. For example, children initially only understand sincere communicative acts and only later on in their development do they start comprehending, for example, deceit and irony. Children's ability to deal with mental representations and inferential chains of increasing complexity develops with age, and this fact helps explain the development of their pragmatic competence.

From this perspective, the increasing capacity to construct and manipulate complex mental representations is involved in the emergence of preschoolers' and kindergarten student's capacity to deceive. A deceptive task could be made easier to comprehend by reducing the number of characters, episodes, and scenes involved in the task, and by including a deceptive context (Sullivan *et al.*, 1994).

Likewise the ability to comprehend and produce different forms of ironies involves an increasing and sophisticated inferential ability. Lucariello and Mindolovich (1995) carried out a study on the ability of 6- and 8-year-old children to provide ironic endings to unfinished stories. The authors claimed that the recognition and the construction of (situational) ironic events involve the ability to manipulate the representations of events. These representations have to be critically viewed, and disassembled in order to create new, different, and ironic event structures. Also, different forms of irony behave in different ways, as the authors' experiments show. Their results show that older children construct more complex ironic derivations from the representational base than younger children do.

Just as it is possible to better understand the development of pragmatic competence by considering the cognitive processes involved in a specific communicative act, it also is possible to explain deficits in performance in cases of brain damage. The ability of children with closed head injury to solve pragmatic tasks is closely dependent (for a review, see Bara *et al.*, 1999b). These subjects performed worse than did their normal peers in specific pragmatic tasks such as bridging the inferential gap between events in stereotypical social situations and tasks such as comprehending utterances that require inferential processes because of their use of idiomatic and figurative language (Dennis and Barnes, 1990).

Cognitive Pragmatics and Brain Damage

Neuropsychological diseases affect communicative performance in various ways, depending on which relevant cognitive subsystem is damaged. The information obtained by studying these abnormal processes provides us with an opportunity to better understand the architecture of the brain/mind and its relationship to pragmatic competence (Tirassa, 1999; Bara and Tirassa, 2000). Acquired brain damage impairs certain cognitive processes while leaving others unaffected. For example, it is well-documented in the literature that aphasic patients with left-brain damage have residual pragmatic competence despite their language impairment (*see* **Language in the Nondominant Hemisphere**).

On the other hand, what different cerebral injuries have in common is a damaged capacity to deal with phenomena that require complex mental processes in order to be understood. In particular, if the tasks require more complex inferences, then this capacity seems to be more damaged than in other cases, as we will show later in this section. Results like these seem to confirm the assumption that different pragmatic phenomena require the activation of increasingly complex cognitive processes.

McDonald and Pearce (1996) found that traumatic brain injured patients (TBI) do not have difficulty in the comprehension of written sincere exchanges such as [9] Mark: *What a great football game!;* Wayne: *So you are glad I asked you?*, but they have several problems, compared to the normal control subjects, in comprehending ironic exchanges such as [10] Mark: *What a great football game!*; Wayne: *Sorry*

I made you come. The authors gave the subjects the same experimental material in auditory form and found that the patients' performance did not improve. The authors concluded that TBI patients have difficulty in comprehending irony and that, even if the tone of voice usually facilitates the comprehension of ironic remarks, it is not sufficient on its own.

Furthermore, McDonald (1999) found that, surprisingly, TBI patients have no problem understanding written ironic utterances such as [11] Tom: *That's a big dog*; Monica: *Yes, it's a miniature poodle*. The author suggested that [11] might require a shorter inferential chain compared to [10] in order to be understood. Indeed, in comprehending [11], it is sufficient to understand what Monica answers as meaning that Tom's statement meant the opposite of what it said. In [10], however, Wayne's response is not only a rejection of the original comment, but an allusion to Mark's actual reaction to the game. Thus, there were at least two necessary inferential steps in the comprehension process. Such findings are in line with the proposal that different kinds of irony may vary in their difficulty of being understood, according to the complexity of the required inferential load (Bara *et al.*, 1999a).

Particularly interesting from our perspective are studies that showed that the decay of pragmatic competence in closed head injured subjects (CHI) reflects the same type of development that is observed in normal children, i.e., the capacities acquired later in the development of the pragmatic ability are the most damaged. Using a linguistic experimental protocol, Bara *et al.* (1997) tested a group of CHI subjects and found that specific pragmatic tasks such as the comprehension of nonstandard communication, e.g., deceit and irony, are more difficult than tasks requiring only simple mental representations, such as the comprehension of standard communication involving only direct, conventional, and nonconventional indirect speech acts. In addition, the authors found no differences in patients' comprehension of direct and conventional indirect speech acts. The same results were observed in the performance of children aged 2 to 6 years old who were tested by the same experimental protocol (Bara and Bucciarelli, 1998). It should also be noted that Bara *et al.* (1997) presented two classical tests on false belief to CHI patients in order to measure their theory of mind, but did not find any significant difference with the control group of children who were not brain damaged. Thus, the patients' poor performance on pragmatic tasks cannot be ascribed to a deficit of the Theory of Mind; that is, their poor performance cannot be ascribed to an inability to understand another person's mental states.

Moreover, Bara *et al.* (2000) used a similar extralinguistic version of the same pragmatic experimental protocol and evaluated the comprehension of standard communication, i.e., simple and complex communicative acts, and nonstandard communication, i.e., deceit and irony. Such a protocol contains videotaped scenes wherein the pragmatic phenomena are presented using extralinguistic means, such as pointing or clapping. The subjects were firstly a group of children 2–6 years of age and secondly a group of Alzheimer's disease patients, and found that children show the same tendency in the development of extralinguistc competence that was observed by Bara and Bucciarelli (1998) in the linguistic domain. In addition, the authors observed a similar tendency toward decay in the Alzheimer's patients' extralinguistic competence: the nonstandard extralinguistic tasks are understood less well than are the standard communicative tasks. Finally, the trend of decaying pragmatic competence in the Alzheimer patient group matched the results obtained by CHI patients, when tested according to the same extralinguistic protocol (Bara *et al.*, 2001). The CHI subjects were also given several neuropsychological tests, but no statistical correlation between the subjects' performance on the pragmatic protocol and their performance on these collateral neuropsychological tests was found. Thus, the patient's poor performance cannot be ascribed to a deficit in their executive functioning.

As already observed for the development of pragmatic linguistic and extralinguistic competence, the empirical data concerning brain damaged subjects seem to be in favor of the existence of a unified pragmatic competence which is independent of the input – whether it is linguistic or extralinguistic. That is, the comprehension of speech acts and extralinguistic communicative acts shares the most relevant mental processes when tested on different pragmatic phenomena, and the pragmatic competence seems to be independent of the expressive means used to realize it.

Cognitive Pragmatics and the Executive Function

While the literature provides empirical evidence that mental processes involved in various pragmatic tasks can be ordered according to increasing difficulty, as we have seen above, in order fully comprehend pragmatic competence from a cognitive perspective, we need to consider also a further factor affecting the human ability to communicate: the executive functions.

The Executive Function is a cognitive construct used to describe the goal-directed behaviors that are mediated by the frontal lobes. The Executive

Function guides a person's actions and enables him to behave adaptively and flexibly; it includes cognitive capacities such as planning, inhibition of dominant responses, flexibility, and working memory.

Barnes and Dennis (2001) have shown that, in addition to a deficient inferential ability, also a reduction of working memory and metacognitive skills may be invoked to explain closed-head injured children's problems in comprehending stories. Working memory provides the necessary resources for computing inference in ongoing text comprehension; metacognitive skills are used when checking if, and when, an inference needs to be made. The authors tested children with severe to mild head injury on their ability to comprehend brief written stories, and found inferencing deficits in children with severe (but not with mild) head injury; these children had problems linking their general knowledge to the particular wording of the text. In general, when the metacognitive demands and the pressure on working memory were reduced, children with severe head injuries did not show any deficiencies in inferencing compared to the development in normal children or their mildly head-injured peers. Working memory also plays a role in explaining the poor ability to comprehend written stories that is observed in children with hydrocephalus, a neuro-developmental disorder accompanied by increased pressure of the cerebrospinal fluid on the brain tissue. Children with hydrocephalus, when compared to the control group, show increasing difficulty drawing on information from an earlier read sentence when trying to understand a new sentence, the greater the distance between the two texts. Thus, while these children do not seem to have a fundamental problem in making inferences, their poor performance is mainly due to a deficit in their working memory (Barnes *et al.*, 2004).

As to the role of other executive functions, Channon and Watts (2003) examined the ability of CHI patients to comprehend brief vignettes involving pragmatic judgement and the relationship between this activity and some executive functions: working memory, inhibition, and the ability to organize and plan appropriate responses in a certain context. The authors found that only the ability to solve the inhibition task, which required the subjects to inhibit dominant words and generate words that completed sentences with nonsensical endings, correlates with the pragmatic comprehension task. No association was found with the other executive skills.

From a neuropsychological perspective, intact frontal lobes are critical to executive functioning, and because traumatic brain injury often results in damage to these areas, pragmatic deficits shown by these patients can be explained by a principal Executive Function impairment. From this perspective, the deficits in planning and monitoring of behavior that are usually observed in such patients seem to explain the difficulty these subjects have in adhering to the structure of conventional discourse (McDonald and Pearce, 1998).

To conclude, theoretical and empirical studies in the literature seem to suggest that in order to explain people's pragmatic competence, it is necessary to take into account the role played by at least three elements: mental processes, namely, the inferential load and the complexity of the mental representations; the Theory of Mind; and the Executive Function whereas the empirical studies mainly focus on the linguistic competence that is needed to realize various pragmatic tasks, the perspective should be widened to include a methodical comparison with extralinguistic competence. In order to establish whether, or not, the cognitive components that make these two different means of communication are the same in both cases. Finally, a complete theory in the cognitive pragmatic domain should be able to explain not only adult normal subjects' ability to communicate, but also the development and the decay of this capacity in brain-damaged patients.

Much contemporary philosophy of language can be viewed as a synthesis of three major traditions: ideal language philosophy, ordinary language philosophy, and cognitivism. In the first three-quarters of the 20th century, philosophers in both the ordinary and ideal language traditions sought to solve or dissolve traditional philosophical problems through careful exegesis of the meanings of words and sentences. For ideal language philosophers, the project was to formally describe how words and sentences ought to be interpreted in scientific and philosophical discourse. For ordinary language philosophers, the project was to characterize the conventions underlying the actual use of words and sentences in ordinary speech. Philosophers in both traditions made a number of lasting contributions to the philosophical and scientific study of language, but they were not just studying language for its own sake. Many philosophers in this period considered the philosophy of language to be first philosophy, the foundation on which other philosophical inquiries are built, and they had other philosophical issues in mind when developing their accounts of language (*see* **Epistemology and Language; Metaphysics, Substitution *Salva Veritate* and the Slingshot Argument**).

Cognitive Science and Philosophy of Language

S Scott, Washington University in St. Louis, St. Louis, MO, USA

© 2006 Elsevier Ltd. All rights reserved.

Much contemporary philosophy of language can be viewed as a synthesis of three major traditions: ideal language philosophy, ordinary language philosophy, and cognitivism. In the first three-quarters of the 20th century, philosophers in both the ordinary and ideal language traditions sought to solve or dissolve traditional philosophical problems through careful exegesis of the meanings of words and sentences. For ideal language philosophers, the project was to formally describe how words and sentences ought to be interpreted in scientific and philosophical discourse. For ordinary language philosophers, the project was to characterize the conventions underlying the actual use of words and sentences in ordinary speech. Philosophers in both traditions made a number of lasting contributions to the philosophical and scientific study of language, but they were not just studying language for its own sake. Many philosophers in this period considered the philosophy of language to be first philosophy, the foundation on which other philosophical inquiries are built, and they had other philosophical issues in mind when developing their accounts of language (*see* **Epistemology and Language; Metaphysics, Substitution *Salva Veritate* and the Slingshot Argument**).

As the limitations of the ordinary and ideal language traditions became apparent and their influence began to decline, the cognitivist tradition in the scientific study of language was growing. Cognitivists view the mind as a computational and representational system and bring a wide variety of empirical evidence to bear on their investigations into the structure and processing of linguistic knowledge in the mind. The synthesis of cognitive science and philosophy of language, or as I shall call it, the new philosophy of language, integrates the formalisms of the ideal language tradition with the careful attention to the nuances of use that characterized the ordinary language tradition. But as cognitivists, many contemporary philosophers of language also take results from linguistics into account and share with other cognitive scientists a commitment to producing theories that are consistent with available psychological and neuroscientific evidence. What follows is a very brief account of the three traditions and their synthesis into the new philosophy of language, ending with a review of some recent work on proper names that exemplifies this new synthesis.

The Ideal Language Tradition

Ordinary speech is a rich source of vagueness, ambiguity, puzzles, and paradoxes, most of which go unnoticed by most speakers. This may not matter all that much for the purposes of ordinary conversation, but in scientific and philosophical discourse the imprecision of ordinary language is not to be tolerated. So said Bertrand Russell, Gottlob Frege, W. V. O. Quine, and the philosophers of the ideal language tradition (*see* **Frege, Gottlob (1848–1925)**; **Quine, Willard van Orman (1908–2000)**; **Russell, Bertrand (1872–1970)**). According to them, ordinary language contains certain deficiencies and the philosopher's job is to provide remedies (Russell, 1919: 172, describes one such "deficiency" as a "disgrace to the human race"). The goal of these philosophers was to standardize and regiment language, explain away puzzles and paradoxes, and formally characterize ambiguities. Their aim was to transform ordinary language into something closer to an ideal language – one that scientists and philosophers could use to express their hypotheses about the world. The strengths and weaknesses of their approach can be illustrated using Russell's theory of proper names.

Example: Proper Names

The idea that scientific hypotheses are about the world was key for the ideal language philosophers. Sentences in science and philosophy, not to mention ordinary conversation, often attribute properties to objects in the real world (*see* **Objects, Properties, and Functions**). Accordingly, a defining feature of ideal language philosophy was the idea that the relationship of reference is a basic unit of meaning (*see* **Reference: Philosophical Theories**), and the starting point was the analysis of simple property attribution sentences such as:

(1a) Venus is round.
(1b) Venus is a star.

Here are some basic intuitions: Sentence (1a) is true because the planet Venus has the property of being round, and sentence (1b) is false because the planet Venus does not have the property of being a star.

Here is a simple analysis that respects those intuitions: In both sentences, the proper name *Venus* refers to an object (*see* **Proper Names: Philosophical Aspects**; **Proper Names: Semantic Aspects**), the remaining words *is round* and *is a star* attribute properties to that object, and the sentences refer to the propositions that Venus is round and that Venus is a star, respectively (*see* **Propositions**). This analysis is shown more formally in (2), where VENUS denotes the actual object Venus, not a word or an idea.

Simple Analysis of (1)

(2a) *round*(VENUS)
(2b) *star*(VENUS)

This analysis of simple sentences can be developed into a powerful system for characterizing the semantics of much more complex and interesting sentences. But, unfortunately, it also runs into fatal problems with certain sentences that seem just as simple as those in (1). For instance, it is not easy to see how to extend the analysis to cover:

(3) Vulcan is round.

This sentence was once thought to be true by astronomers who postulated the existence of a planet, tentatively named *Vulcan*, to explain the observed perturbations in Mercury's orbit. It is now known that there is no such planet or, to put it another way, that *Vulcan* is an empty name (*see* **Empty Names**). So, although (3) is clearly meaningful and has a grammatical form that parallels the sentences in (1), the simple analysis will not work in this case. Recall that (1a) is true because the object referred to by the name *Venus* has the property of roundness. But in (3), there is no object named *Vulcan* and therefore nothing to which any such property can be applied.

Here we have the makings of a puzzle – if reference is as basic to meaning as it appears to be, then how is it possible to say meaningful things using words that have no referents? One option is to allow that

nonexistent things such as Vulcan, Santa Claus, unicorns, and so on really do have some kind of objecthood. But most philosophers would reject this option because, as Russell (1919: 169) put it, "logic ... must no more admit a unicorn than zoology can; for logic is concerned with the real world just as truly as zoology." Another option is to just bite the bullet and accept that (3) does not express a proposition and is therefore meaningless. Although some contemporary philosophers of language have taken this route (e.g., Adams and Stecker, 1994), the ideal language philosophers did not want to take that way out either because to do so would be to render many important scientific and philosophical hypotheses meaningless.

Russell's Theory of Descriptions

Russell found a solution to the problem of empty names (and other philosophical puzzles) in his theory of descriptions (*see* **Descriptions, Definite and Indefinite: Philosophical Aspects**). Briefly, Russell held that names such as *Vulcan* and *Venus* do not directly refer but instead are shorthand for definite descriptions such as *the planet causing perturbations in Mercury's orbit* and *the second planet from the sun*, respectively. That is, names are disguised definite descriptions. So, when scientists utter sentences such as those in (1) and (3), what they assert is something more like:

Step One of Russell's Analysis of (1) and (3)

(4a) The second planet from the sun is round.
(4b) The second planet from the sun is a star.
(4c) The planet causing perturbations in Mercury's orbit is round.

On the face of it, it looks like (4c) has the same problem as (3) – descriptions such as *The planet causing perturbations in Mercury's orbit* seem like they should be interpreted as namelike referring expressions. But Russell did not think so. He thought that descriptions such as these should be analyzed as general, quantificational statements about what exists in the world. In the case of (4c), the correct interpretation, according to Russell, is that there is exactly one planet causing perturbations in Mercury's orbit and all such planets are round. This analysis is expressed in quantificational notation in (5), where *pm*() stands for the property of being a planet that causes perturbations in Mercury's orbit. (Some of the inessential details have been simplified in a way that Russell might have objected to, but that does not matter for current purposes.)

Step Two of Russell's Analysis of (3)

(5a) There exists exactly one planet x that is the cause of the perturbations in Mercury's orbit, and it is round.
(5b) $\exists x\ ((\ \forall y\ (\ pm(y) \leftrightarrow y = x\ ))\ \&\ round(x))$

In this final analysis, there is no longer any element in the proposition corresponding to the name *Vulcan* and no role available for any referent, and thus the puzzle of empty names disappears. To recap: Names are shorthand for disguised definite descriptions, and sentences that contain definite descriptions express general propositions about the world and the things in it rather than singular propositions about particular entities.

Limitations of the Ideal Language Approach

Russell's analysis of proper names, as clever and influential as it is, runs afoul of ordinary intuitions. Sentence (3) seems to have a very simple subject-predicate form, but the proposition in (5) that provides the meaning for (3) bears no resemblance to that form. Furthermore, (5) is false because it asserts the existence of something that does not exist (i.e., it asserts the existence of a planet that causes perturbations in Mercury's orbit, but there is no such planet). But it is not clear to everybody that (3) really is false (see Strawson, 1950; and the reply by Russell, 1957). To many people, questions such as *Is Vulcan round?* have the same kind of problem as questions such as *Have you stopped cheating on exams yet?* – to answer either "yes" or "no" would be to accept a problematic premise.

Russell was not driven to this analysis of simple sentences as an attempt to characterize how ordinary speech works but as an attempt to dissolve an apparent logico-scientific puzzle that arises when we take the referential commitments of ordinary speech seriously. But the analysis ends up providing no account of the fact that people seem quite capable of making what appear to be true claims about nonexistent things.

(6a) Santa Claus usually wears a red suit.
(6b) Pegasus looks a lot like a horse.

Russell's theory of disguised definite descriptions makes the sentences in (6) come out false, contrary to most people's intuitions. His theory preserves the apparent meaningfulness of these sentences, and does so without maintaining any problematic commitments to entities such as Pegasus and Santa Claus, but at the price of a theory that may not have much to say about their ordinary use.

The Ordinary Language Tradition

As vague, ambiguous, and rife with semantic puzzles as ordinary language is, it also contains a wealth of information that philosophers cannot afford to ignore. In order to discover anything meaningful about important philosophical topics such as Truth, Knowledge, and Justice, philosophers need to know what *truth, knowledge, justice*, and other related words actually mean in ordinary language. This was the perspective of Gilbert Ryle, H. P. Grice, J. L. Austin, P. F. Strawson, Ludwig Wittgenstein (in his later works), and the philosophers of the ordinary language tradition (*see* **Austin, John Langshaw (1911–1960); Grice, Herbert Paul (1913–1988); Strawson, Peter Frederick (b. 1919)**). According to them, philosophers must pay careful attention to the nuances of ordinary language use and must be particularly wary of misusing ordinary language expressions in their philosophical theories. In many ways, this tradition was radically opposed to the ideal language tradition: whereas the ideal language project was a prescriptive project, concerned with legislating how language ought to be understood, the ordinary language approach was purely descriptive, concerned with the investigation of how language is actually used; whereas ideal language philosophers sought to construct a theory of meaning based on reference to things in the world, ordinary language philosophers sought to construct a theory of meaning based on conventions of ordinary use (*see* **Use Theories of Meaning**). But despite these differences, both traditions shared a common motivation, namely, the analysis of language in order to help solve or dissolve philosophical problems. It is just that in pursuing this common aim, ideal language philosophers were busy constructing a new language while ordinary language philosophers were busy pointing out how philosophers tended to misuse the old one.

Example: Ryle on Free Will

Ordinary language philosophers thought that the meaning of an expression is the conventions governing its use. Thus, to get at the meaning of an expression, we have to examine how it is ordinarily used. The standard technique is to assemble a list of sentences containing a given expression and then try to find conditions under which it would be inappropriate or nonsensical to use those sentences. Whatever those conditions turn out to be, their negation must be part of the meaning of the word in question. (Notice that this makes short work of the puzzle of empty names. Because the meaning of a word is the conventions governing its use, names can have meaning whether they have a referent or not.)

As an example of ordinary language analysis in action, consider Ryle's (1949) investigation of the word *voluntary*. Ryle noted that philosophers often characterize free will (another important philosophical topic) based on the distinction between voluntary and involuntary actions – free will is said to be involved in an action when it is performed voluntarily and not when it is performed involuntarily. So *voluntary* (along with grammatical variants such as *voluntarily*) is an important word in philosophy, but what does it actually mean in ordinary language? Consider the following sentences:

(7a) Benazir went to school voluntarily.
(7b) Hussein ate the sandwich voluntarily.
(7c) Ahmad watched *Seinfeld* voluntarily.

As Ryle observed, such uses of *voluntary* and its grammatical variants seem odd or wrong in any situation in which there is no reason to believe that the person in question ought not to have performed the action. So if Benazir has been banned from campus or hates school or is supposed to be doing something else, then (7a) might make sense. But if there is no reason to suppose anything like that, then the word *voluntarily* should be left out. Ditto for (7b) and (7c). From these sorts of considerations, Ryle concluded, part of the meaning of the word *voluntary* must include the condition that it can only be used in the description of an action that for some reason ought not to have been performed.

To bring this back to the philosophical problem of free will, Ryle noted that philosophers who worry about what it could mean to eat a sandwich or watch *Seinfeld* voluntarily, absent any kind of context, are systematically misusing ordinary English. As he put it, they engage in an "unwitting extension of the ordinary sense of 'voluntary' and 'involuntary' " (Ryle, 1949: 69). The conclusion that Ryle drew from these and other considerations was that there is no problem of free will. The appearance of the problem arises only when philosophers misuse ordinary language words such as *voluntary*. The whole problem just dissolves under ordinary language analysis.

Limitations of the Ordinary Language Approach

The ordinary language philosophers tended to be less likely to make use of formalisms for characterizing the meanings of words or sentences. The nature of ordinary language analysis was such that it produced accounts of word or sentence meaning that tended to be less rigorous than those produced by philosophers working in the ideal language tradition. Furthermore, the use theories of meaning pursued by ordinary language philosophers had little to say about the relationship between language and reality,

and were thereby limited in their ability to account for reference and truth conditions, whether in scientific, philosophical, or ordinary discourse. The ordinary language philosophers demonstrated many of the important and subtle ways in which philosophically interesting words are employed in ordinary language, but they did so at the price of having neither a systematic, precise account of meaning nor a theory of the relationship between language and the world.

The ordinary language tradition ultimately met its demise at the hands of its own adherents. In his 1967 lectures on 'Logic and Conversation,' Grice (1989) gave a strong voice to many philosophers' growing misgivings about the project. He argued for a sharp distinction between what is said by a speaker on a particular occasion and what the speaker might have meant by what was said. For Grice, what is said is the literal, truth-evaluable, relatively invariant portion of meaning. To use one of his examples, suppose Alyssa happens upon Cliff, who has run out of gas on the highway, and utters:

(8) There's a gas station around the corner.

What Alyssa has said, in Grice's sense (literally expressed, truth-conditional meaning) is the proposition that around the indicated corner is a gas station. Alyssa said nothing further about whether the gas station is open, has gas to sell, and so on. But assuming she is sincerely trying to help Cliff out, it will be inappropriate for her to use that sentence unless she believes that the gas station is open and has gas to sell. Based on this latter observation, an ordinary language philosopher might be tempted to conclude that these further conditions are part of the meaning of (8). But that, Grice argues, is a mistake.

Grice's alternative is that the further propositional content about the gas station being open and having gas to sell is not part of the literal meaning of (8), but is what he called a conversational implicature (*see* **Implicature**). This conversational implicature is part of what Alyssa means to communicate with (8), but she expects Cliff to be able to pick up on it without requiring her to state it explicitly. The details of how Cliff might do that is beyond the scope of the current discussion (see Grice, 1989; Sperber and Wilson, 1995), but to get a sense of the reasonableness of the distinction between what is said and what is conversationally implicated, consider how Alyssa could have tacked an extra clause onto (8) to take back both what she implicated and what she said.

Clauses That Cancel Implicatures

(9a) There's a gas station around the corner, but it's not open.
(9b) There's a gas station around the corner, but it's out of gas.

The sentences in (9) both have (8) embedded in them, and the fact that they do not seem contradictory indicates that the material in the final clause must not be opposed to any part of the meaning of (8). Now suppose Alyssa had instead uttered one of the sentences in (10).

Clauses That Contradict What Is Said

(10a) There's a gas station around the corner, but it's not a gas station.
(10b) There's a gas station around the corner, but it's not around the corner.

The fact that these sentences are clearly contradictory indicates that the added clauses must be opposed to some part of the literal meaning of (8). So there is strong intuitive support for the distinction between what Alyssa has said, as shown by the contradictory clauses in (10), and what she conversationally has implicated, as shown by the noncontradictory clauses in (9).

On the basis of this distinction, Grice argued for caution when moving from facts about how words are used to facts about the meanings of those words. It would have been inappropriate for Alyssa to utter (8) if she thought the gas station was closed, but that does not tell us anything about what (8) means. Evidence about use can, in principle, indicate something about the literal meaning of words and sentences, but not always in such a simple way. Ryle, in particular, was probably wrong to jump from facts about the use of the word *voluntary* to facts about its meaning (and then to the denial of the problem of free will). Grice thought that ordinary language analysis could still be useful but that philosophers needed to pay more attention to separating what an expression can be used to communicate from what that expression actually means in the language – a project that turns out to be exceedingly difficult (*see* **Semantics–Pragmatics Boundary**).

The Cognitivist Tradition

Language is a fascinating topic of study in its own right, regardless of its role in helping philosophers do their work. It is now clear that the production of even very simple speech behaviors is far more complex than was once thought and working out how linguistic knowledge is structured and processed in the human mind should be a central goal in the scientific study of language. That is what linguists working in the cognitivist tradition tend to think. According to them, the goal of linguistic inquiry is not primarily to account for reference and truth or to characterize conventions of use but rather to find out what it is

about the human mind that makes language what it is. Cognitivism is actually a cross-disciplinary tradition concerned with the study of the human mind in general, not just language. Leading figures in the birth and early development of the cognitivist tradition included computer scientists (e.g., Marvin Minsky; psychologists (e.g., George Miller), linguists (e.g., Noam Chomsky; *see* **Chomsky, Noam (b. 1928)**), and philosophers (e.g., Hilary Putnam, Jerry Fodor, Daniel Dennett; *see* **Fodor, Jerry (b. 1935)**).

There are four features that, taken together, loosely define the cognitivist approach to the study of mind and language: (1) an adherence to computational and representational theories of mind, (2) a rejection of most forms of behaviorism, (3) an openness to empirical evidence from a wide variety of sources, and (4) a tendency toward identifying linguistic meanings with mental states rather than with things in the world or patterns of ordinary use. Each of these aspects is discussed next.

Computational and Representational Theories of Mind

Cognitivists model the mind/brain as an information processing system that performs computations on structured representations of the world. In other words, the mind/brain is a kind of computer, analogous in many ways to a digital computer. Many people find this claim jarring at first, but actually it is quite natural to suppose that, at least in some circumstances, people use computers to do their thinking for them. Whenever an accountant uses a spreadsheet to prepare tax forms, a pilot flies using an automatic guidance system, or a librarian searches an electronic catalog, computers are being used to perform tasks that would require mental effort if performed by human beings. When people use a computer to perform a task, they avoid some of the thinking that would have been required if they had performed the task unaided.

Digital computers accomplish their apparently mental feats by executing algorithms that manipulate data structures. An algorithm is a set of fully explicit, step-by-step instructions for accomplishing a given task, and a data structure is a package of information about some aspect of the world. For example, a data structure might contain information about a social hierarchy, the layout of a city, or the structure of a sentence. Algorithms contain instructions for how to use those data structures to decide, for example, who to approach for a loan, how to get from downtown to the suburbs, or what a speaker might mean by uttering a particular sentence. Cognitivists claim that human thought consists of computational processes (analogous to algorithms) that operate on mental representations of the external world (analogous to data structures), although there remains much debate over the nature of those processes and representations.

Like a digital computer, the mind/brain can be analyzed at a number of different levels (Dawson, 1998; Marr, 1982). At the physical level, digital computers are instantiated in electronic circuitry and minds are instantiated in brains. By investigating the brain, we can figure out what kinds of mental representations and computational processes it supports and what parts of it may or may not be involved in language. At the algorithmic level, digital computers run programs that specify the details of their behavior. The bold conjecture of cognitive science is that minds are the programs that run on the physical circuitry of the brain. By performing psychological experiments, we can shed light on how linguistic knowledge is represented in the mind and what computational processes are involved in using that knowledge (*see* **Psycholinguistics: Overview**). Finally, there is the task level. The programs that digital computers run can only be made sense of in light of knowledge about their connections to the world and the tasks they were designed to solve. Similarly, in order to understand how the mind uses language, it is necessary to have a theory of what language is and what knowledge is involved in language use.

These three levels of analysis thus define a multidisciplinary program of research into the nature of human language, with different research questions posed at each level (see Table 1). Cognitivist linguists focus most of their attention on the algorithmic and task levels, concentrating on the difficult problems of identifying the knowledge required to produce well-formed grammatical utterances, determining how that knowledge must be represented in the minds of the speakers, and identifying which elements of that knowledge are learned and which are innate (*see*

Table 1 Three-level research program

Level	*Questions*
Task	How are natural languages structured? What must people know and what must they know how to do in order to produce and understand human speech?
Algorithmic	How is knowledge of language represented in the mind? What computational processes are involved in producing and understanding speech?
Physical	How are these representations and computational processes implemented in the hardware of the brain?

Innate Knowledge). But as cognitivists, they remain open to, and sometimes make use of, evidence from the physical level as well.

The Rejection of Linguistic Behaviorism

Prior to the establishment of the cognitivist tradition in the 1960s and 1970s, the dominant approach to the study of the mind and language was behaviorism. Many philosophers at the time endorsed or were influenced this approach, including prominent representatives of both the ideal language and ordinary language traditions. Behaviorism comes in a number of varieties (*see* **Behaviorism: Varieties**), but what all behaviorists agree on is a rejection of internal mental states as something that can be scientifically studied or appealed to in explanations of language and behavior. For psychologists such as B. F. Skinner, this meant that linguistic behavior was to be explained as a complex pattern of responses to environmental stimuli. Verbal responses were thought of as being under the control of certain stimuli in the environment (Skinner, 1957).

Skinner's view of language was subjected to ruthless criticism from Chomsky, who pointed out the complexity of linguistic behavior and the wide variety of possible responses to a given stimulus:

> A typical example of stimulus control for Skinner would be the response to … a painting with [the utterance] *Dutch*… Suppose instead of saying *Dutch* we had said, *Clashes with the wallpaper*, *I thought you liked abstract work*, *Never saw it before*, *Tilted*, *Hanging too low*, *Beautiful*, *Hideous*, *Remember our camping trip last summer?* (Chomsky, 1959, p. 31)

Once the nonstimulus-bound nature of linguistic behavior is fully appreciated, said Chomsky, the prospect of arriving at an account of linguistic behavior without involving an appeal to mental states is completely hopeless. Cognitivism pointed the way out of behaviorism by providing a method of formally characterizing those mental states.

The Open Evidence Base

The cognitivist tradition is an empirical tradition. The sources of evidence available to the linguist include the judgments of native speakers, the process of first-language acquisition, the controlled psychological study of speech production and comprehension, the study of acquired and genetic language deficits, and the study of the neurological features of language use in healthy adults, to name but a few. These sources of evidence can be used to investigate language at the task, algorithmic, and physical levels (see Table 2). This is not to say that it is the current practice of linguists to make use of all of these sources of evidence. Indeed much work in theoretical linguistics proceeds using only the grammaticality judgments of the linguists themselves. But there is a general commitment both to the idea that a complete theory of language has to be consistent with all these sources of evidence and to the idea that the evidence base for linguistics is open – that is, there are no principled limits on the kinds of evidence that might bear on the structure of linguistic knowledge.

Table 2 Sources of evidence for the three levels

Level	*Example sources of evidence*
Task	Judgments of native speakers
	Which strings of words are grammatical and which are not?
	What meanings can a sentence have and not have?
Algorithmic	Developmental psychology
	How do children acquire language?
	What are the common patterns of language development?
	Cognitive psychology
	How do adults react to linguistic stimuli under controlled conditions?
Physical	Clinical studies
	What kinds of brain injuries and diseases cause language deficits?
	What specific language deficits are caused by specific brain injuries and diseases?
	Anatomical and functional studies
	What parts of the brain are involved in language use?
	How are these parts interconnected?

The commitment to an open evidence base has important consequences. For behaviorists, the study of language had to be grounded in observable behavior only. As Quine (1960) pointed out, it turns out that this leads to the conclusion that linguistic knowledge and meaning cannot be unambiguously determined. From this, he drew the conclusion that there is simply no fact of the matter about how to specify the mapping from words and sentences to their meanings (*see* **Indeterminacy, Semantic**). A famous response to Quine, again from Chomsky (1969), is based on the notion of the open evidence base. According to Chomsky, Quine reached his radical conclusions about semantic indeterminacy by accepting in advance the behaviorist notion that only observable behavior and responses to environmental stimuli may be used as the data for theories of linguistic meaning. But, as Chomsky points out, no other science places such *a priori* limits on the kinds of evidence that can be used to decide between competing theories. As long as the evidence base in linguistics remains open, the possibility of discovering further evidence that will help determine linguistic meaning is open as well.

Meanings as Mental States

The establishment of a viable theory about mental states and mental processing opened the door to a new class of theories of linguistic meaning based on the pairing of words in the public language with mental states of speakers. The general idea of a mental state theory of meaning is at least as old as Aristotle (*see* **Aristotle and Linguistics**), but the computational and representational theory of mind gave it new life by providing a story about what mental states might be like and how they might be processed in the mind. In addition to endorsing a mental state account of meaning, some cognitivists also harbor a deep mistrust of the reference-based theories pursued in the ideal language tradition. The semanticist Ray Jackendoff (2002) argues that the only kind of reference a cognitivist theory of language can countenance is reference to other mental states (*see* **Jackendoff, Ray S. (b. 1945)**), whereas Chomsky (2000) suggests that reference, as originally construed by ideal language philosophers, is not a suitable topic for scientific inquiry at all.

Jerry Fodor (1975) has proposed that words and sentences come by their meaning through being paired with internally represented formulae in what he calls the Language of Thought (*see* **Language of Thought**), or Mentalese (*see* **Mentalese**). Mentalese is not a public language such as English. It is more like a computer language – a formal system with a combinatorial syntax and an expressive power that equals or surpasses that of a public language. Fodor proposes that words and sentences express mental states, but, unlike Chomsky and Jackendoff, he takes the further step of attempting to scientifically characterize the meanings of expressions in Mentalese as relationships to objects and properties in the external world (*see* **Representation in Language and Mind; Causal Theories of Reference and Meaning**). Fodor's theory of meaning thus has two parts: (1) words inherit their meanings from the mental states they express, and (2) most of those mental states get their meanings through reference to the external world. An important alternative cognitivist account of meaning as mental states is offered by connectionism, although a full discussion of that approach is beyond the scope of this article (*see* **Human Language Processing: Connectionist Models**).

The Limitations of Cognitive Science

It is not yet clear how far cognitive science can go, and there are philosophers who dispute the claim that studying the structure and processing of linguistic knowledge in the human mind can tell us much about the nature of language itself (see Barber, 2003). But the computational and representational theory of mind, as a working hypothesis, has given rise to a productive research program producing theories of mind and language rich and predictive enough that, at the very least, they should not be ignored. The cognitivist approach to the study of mind and language is widely regarded by philosophers as the only approach currently worth taking seriously.

The New Philosophy of Language

The new philosophy of language emerged in the 1970s as a synthesis of the ideal language, ordinary language, and cognitivist traditions. From the ideal language tradition comes the use of rigorous formalisms and a concern for the connection between language and reality. From the ordinary language tradition comes the descriptive nature of the project and careful attention to the nuances of ordinary use, as well as Grice's distinction between what is said and what is implicated by an utterance. And from the cognitivist tradition comes an adherence to computational and representational theories of the mind, a rejection of linguistic behaviorism, an attention to the mental states of the language user, and a concern with making semantic and pragmatic theories consistent with the relevant empirical results concerning language and the mind.

The boundaries between linguistics and the philosophy of language have become blurred in this new synthesis. Whereas phonology (the sounds of language), morphology (the structure of words), and syntax (the structure of sentences) remain a concern mostly of linguists, semantics (the meaning of language) and pragmatics (the communicative use of language) are studied by both linguists and philosophers. There has also been considerable cross-fertilization between linguistics and philosophy. Linguists have adopted the formalisms of the ideal language tradition and the Gricean view of the relation between semantics and pragmatics that arose out of the ordinary language tradition. Philosophers, on the other hand, have adopted the linguistic account of syntax and feel an obligation to relate the semantic interpretation of a sentence to its syntactic form. In addition, the cognitivist approach to linguistics also throws up a host of difficult conceptual issues that demand a rigorous philosophical treatment (*see* **Philosophy of Linguistics**), for example, the place of reference in semantic theory (*see* **Externalism about Content**), the nature of linguistic knowledge (*see* **Innate Knowledge; Tacit Knowledge**), and the connection between language and thought (*see* **Thought and Language: Philosophical Aspects**).

Two More Theories of Proper Names

How might a practitioner of the new philosophy of language tackle a traditional semantic problem such as the content of proper names? Two theories of proper names are presented by Tyler Burge (1973) and Larson and Segal (1995). These two theories agree with one another in many important respects – so much so that we might be tempted to suppose that they are merely variants of one another. But, as Gabriel Segal (2001) points out, there are a number of pieces of relevant evidence from the task, algorithmic, and physical levels of cognitive analysis that may be used to adjudicate between the theories. (A caution: The semantic issue is actually more technical than the following discussion suggests, concerning points of difference between semanticists working in the formal framework of truth-theoretic semantics. Because there is no room to introduce the details of that framework here, the accounts of the rival theories are somewhat sketchy, although, I hope, detailed enough to make it clear how empirical evidence can be used to decide between them.)

Burge's approach to proper names is a variation on Russell's disguised definite descriptions. Burge proposes that proper names are actually a kind of common noun, that is, words such as *table* and *cat* that encode properties that apply to large numbers of objects. In Burge's account, if we have a cat named *Sylvester*, then that object has both the property of being a cat (a property it shares with other cats) and the property of being a Sylvester (a property it shares with other Sylvesters). In defense of this idea, Burge points out that, like common nouns, names can be pluralized and paired with determiners such as *the* and *a*:

(11a) There are very few Sylvesters in the world.
(11b) There were three Madelines at the party.
(11c) There's a Bartholomew Kropotnik here to see you.
(11d) The Jessica I met today was a real jerk.

This idea encounters an immediate difficulty. Burge says that names are common nouns, even when they occur unmodified and on their own:

(12) Fido wants to chase Sylvester.

But other common nouns cannot be used that way in English:

(13) *Dog wants to chase cat.

Sentence (13) only works if we interpret *dog* and *cat* as unusual names rather than as common nouns. So proper names seem to be unlike common nouns in at least this respect. Burge resolves the discrepancy by suggesting that bare, unmodified names actually have hidden determiners attached. A name such as *Fido*, when used on its own is, unbeknown to the speaker, actually the phrase *That Fido* or *The Fido* in disguise.

The rival view is Segal's contention that proper names are not common nouns but instead are a special kind of word, paired in each speaker's mind with a special kind of mental representation – an individual concept. These individual concepts are mental representations that encode information about the individuals named. So the name *David Bowie* is paired with an individual concept of David Bowie, perhaps containing the information that he sings, plays the saxophone, is married to a runway model, has probably had plastic surgery, and so on. Names, in Segal's account, are not at all like common nouns, encoding predicates that can apply to more than one person. Rather, they are labels that attach to conceptual information about particular individuals. There are not many David Bowies sharing one name. Rather, there are potentially many names *David Bowie*, each linked to a different individual concept.

Empirical Evidence

It might seem that in the end, the differences between the two theories do not amount to much. Burge says that the name *Fido* can be applied to anything that is a Fido, whereas Segal says that it only applies to one individual and that the reason why there seem to be so many Fidos is that there are many names for distinct individuals that happen to sound the same (call these names $Fido_1$, $Fido_2$, etc.). Is there any real difference between these two theories? A behaviorist such as Quine might be inclined to think that, as long as each can be integrated into a larger theory of equal power in predicting linguistic behavior, then there is no fact of the matter about which is correct. But a cognitivist would rather suppose that there is a way to tell how the language system works, reflected in the biology and psychology of language, and that at most only one of the two suggestions can be correct. And it seems, at least at first glance, that the evidence from the task, algorithmic, and physical levels supports Segal's theory over Burge's.

At the task level, cognitivists consult the intuitions of native speakers to determine the characteristics of the language that they speak. In the case of proper names, the two theories under consideration make different predictions about the syntax of English. Burge's theory predicts that bare names actually have a hidden determiner word attached to them. But this view has some trouble accounting for common intuitions about how names and common nouns

can be used. For example, why is it that determiners can go unpronounced when attached to names, but not when attached to common nouns, as shown by (13)? And why is it that sometimes special contexts are required to insert the determiner in front of a name? For example, to the question "Where do you live?" the response in (14a) seems natural whereas (14b) sounds awful. If *Saint Louis* is really short for a phrase such as *that Saint Louis*, then why can we not say (14b)?

(14a) I live in Saint Louis.
(14b) *I live in that Saint Louis.

At the algorithmic level, cognitivists look at psychological evidence regarding how linguistic knowledge is represented and processed. Again, the two theories make different predictions about the psychology of names. Burge predicts that names that sound the same are the same name, whereas Segal predicts that each individual's name is distinct. If Segal is right, there should be evidence that people tend to expect identical-sounding names to apply only to a single individual. Again, there is some evidence that supports Segal's prediction. It seems that children learning English as a first language expect there to be a class of nouns that refer to only one thing and make use of syntactic clues such as the presence or absence of determiners to decide whether to apply new words to other objects or not. For example, when told that a novel object is *wuzzle* (with no determiner), children are reluctant to apply the new word to other novel objects, even when they are highly similar to the original. But when told that the novel object is *a wuzzle*, they will happily generalize the term to other objects that seem to share some salient properties with the original – just like ordinary common nouns.

Burge's theory also predicts that names are **not** a special kind of noun, whereas Segal predicts that they are. If Segal is right, we should expect to find psychological differences between names and common nouns. We might also expect some physical-level differences. (Recall that at the physical level, cognitivists look to neurological evidence for or against the kinds of representation and processing they propose in their algorithmic-level theories.) Again, the evidence seems to support Segal's view over Burge's. As previously noted, children seem to be prewired to look for names as well as common nouns. In addition, psychological studies on adults reveal that proper names are much harder to recall than common nouns, suggesting distinct storage and/or processing. And at the physical level, certain kinds of brain damage can cause people to lose their ability to use proper names while leaving their ability to use common nouns intact, and vice versa (*see* **Aphasia Syndromes**). This strongly suggests that names are a special kind of word stored in a separate area of the brain.

In fact, things are not as bad as all that for Burge's theory. Segal (2001), in his much more complete and sober account, correctly points out that the psychological and neurological evidence is still quite sketchy and open to interpretation. It is quite possible that a committed Burgian could find a way to keep the common noun theory of names alive. The main point of this example has been to show how, in principle, multidisciplinary evidence from all three levels of cognitive analysis can bear on an issue in semantics. Whereas a behaviorist might be content with two theories that are equally good at describing some aspect of linguistic behavior, the new philosopher of language looks deeper to try and find out which theory does a better job of accounting for the cognitive aspects of language.

Final Words

The work on proper names reviewed here nicely illustrates the main features of the new philosophy of language. Burge and Segal's truth-theoretic approach to semantics is as rigorously formal as any theory in the ideal language tradition; the attention to ordinary speaker intuitions in mediating between semantic theories echoes the approach of the ordinary language philosophers; the mentalistic nature of the theory, the formal, computational nature of truth theories, and the openness to evidence from all levels of cognitive analysis clearly places the work in the cognitivist tradition.

But is this new hybrid approach really philosophy of language, or is it just a branch of linguistics or psychology? There are still those who hold out the hope that analysis of language will eventually help with the resolution of issues in other branches of philosophy, even if only in providing a starting point, and most contemporary philosophers of language remain sensitive the philosophical puzzles and paradoxes that drove the ideal and ordinary language philosophers. Indeed, one of the selling points of both Burge's and Segal's theories of proper names is that they can account for the meanings of empty names. But heeding Grice's lesson about the difficulties of determining what is said and heeding the lessons from contemporary linguistics about the complexities of ordinary language, few still believe any philosophical problem will be solved or dissolved with just a little bit of armchair reflection on conventions of use. The new philosophy of language promises progress on some of the difficult traditional problems in philosophy of language (and perhaps on more general philosophical problems) by combining careful

conceptual analysis with detailed attention to empirical results from the scientific study of language, the mind, and the brain.

Cognitive Science: Overview

J Oberlander, University of Edinburgh, Edinburgh, UK

Introduction

Cognitive science is the interdisciplinary scientific study of the mind. Many questions therefore fall within its scope. For instance, how do people perceive the world through their senses? How do they manage to act in a timely fashion in a changing world? How do they solve novel problems? How do they manage to learn new skills? And how do they understand one another? In addressing these questions, most researchers assume that the human mind is some kind of computational device, containing representations. Modeling human language capacities has been a central goal within cognitive science; relevant research draws on a wide range of empirical and

computational methods. This brief overview first characterizes the subject and then sketches a brief history of it. In indicating the current state of play, key issues in mental representation, modularity, and computational architecture are noted, and some current directions in cognitive research are indicated.

Characterizing the Discipline

Christopher Longuet-Higgins is credited with inventing the term 'cognitive science' in 1973 (Darwin, 2004). The term was apparently used in 1975 during a meeting in Abbaye de Royaumont, which hosted a celebrated debate between Noam Chomsky and Jean Piaget. The term covered a then-emerging research field that drew together researchers from diverse backgrounds, including artificial intelligence and computer science, linguistics, psychology, philosophy, the neurosciences, and anthropology. One thing that united these researchers was an interest in the underpinnings of intelligent human behavior and a recognition that researchers in different disciplines, such as linguistics and psychology, were already studying common phenomena, albeit from distinct perspectives. The idea was that, by pooling expertise, deeper understanding could be achieved.

The core objects of cognitive science study are the normal cognitive capacities of a typical adult (Von Eckardt, 1993), so it is most common to experiment on, and model, such individuals. In practice, the majority of experimental participants are probably undergraduate students in the United States, although cognitive science has also benefited greatly from comparative techniques. For instance, comparisons can be made regarding linguistic competence in adults and children (Tomasello, 2000), ability to attribute mental states to others in normal and autistic children (Baron-Cohen *et al.*, 2000), conscious awareness of visual objects in normal adults and in blindsight persons with specific brain lesions (Weiskrantz *et al.*, 1974), problem solving in adults with varying working-memory capacities (Carpenter *et al.*, 1990), generalization abilities in humans and cotton-top tamarins (Hauser *et al.*, 2002), and reading processes in Hebrew and English (Pollatsek *et al.*, 1981).

Whether working with adult normal typical subjects or carrying out one or other type of comparative study, the vast majority of cognitive scientists can be seen to share two substantive assumptions (Von Eckardt, 1993): (1) the human cognitive mind or brain is a computational device (computer) and (2) it is a representational device. Exactly what kind of computer it is remains more open to dispute, as we shall see. However, most would agree with Von Eckardt that a computer is a device "capable of automatically inputting, storing, manipulating, and outputting information in virtue of inputting, storing, manipulating and outputting representations of that information" (Von Eckardt, 1993: 50). A device is taken to be representational if it has states or entities inside it that function as representations; however, there is rather less agreement in the field about what constitutes a representation.

Given that computation and representation are basic to cognitive science, there is clearly a special link between the analytic goals of cognitive science and the synthetic goals of artificial intelligence (AI). Most researchers in AI aim to develop computer programs that help a machine exhibit behavior that, if it were the behavior of a human, would be called intelligent. For instance, some researchers experiment with systems that can participate in natural language dialogues to help users buy products, such as airline tickets. By contrast, most researchers in cognitive science are not in the business of building smarter software (or hardware) agents; rather, they want to know more about human cognitive capacities. However, an important tool in this effort is the use of computational modeling.

If we have a theory of how someone achieves certain performance (such as understanding written words, or solving a novel problem), then a computer-based model can be built to test the theory. If the theory is expressed in terms of algorithms and data structures, a computer model can be given data as input, and both its output behavior and its internal processes can be compared with human behavior and information about the internals underlying that behavior. A computational model has virtues, both theoretical and practical: it requires a theory to be made explicit enough to implement, and it renders that theory testable. Indeed, with explicit theories of sufficient complexity or power, it may well be that a computational simulation is the only way to determine in a timely fashion what the predictions are in some given scenario.

It can therefore be seen that there is two-way traffic between artificial intelligence and cognitive science. AI supplies both terminology and tools, such as algorithms, programs, and simulation environments. Cognitive scientists can use these in their modeling. In the other direction, cognitive scientists develop models of human cognitive capacities that demonstrate that certain computational tasks can be solved under particular conditions, and how these tasks are solved. Such demonstrations can help AI researchers build better systems. It is worth noting, incidentally, that cognitive models of human performance can help builders of computer systems in ways other than by inspiring the design of AI systems. For instance,

by taking human memory limitations into account, specialists in human–computer interaction can build more usable computer interfaces, and they can also use empirical methods borrowed from cognitive science to help evaluate the usability of their systems.

There is one final point to make about the goals of cognitive science. Most cognitive scientists (whatever their disciplinary background) are interested in *how* people carry out particular cognitive tasks. That is, they want to find out what representations and processes underlie the acquisition and execution of the relevant skilled behavior. Some are also interested in *where* the representations and processes are located. On the one hand, this includes neuroscientists, who consider individual behavior and seek to locate the relevant brain areas, neural circuits, and chemical pathways. On the other hand, researchers who study distributed cognition are interested in group behavior, and they seek to locate external representations (such as documents) and processes (e.g., manipulating objects) occurring in the physical environments in which people work and play (Hutchins, 1995). There are connections between this approach and that which focuses on embodied cognition, whereby the (possibly changing) physical properties of an agent strongly influence the development of its cognitive capacities (Clark, 1997).

Yet there is also a recent move toward studying *why* people have specific representations and processes. This is the province of evolutionary psychology (Barkow *et al.*, 1992), which casts the interdisciplinary net even wider than before, and draws on anthropology, archaeology, and paleontology to try to explain why modern humans have, for instance, acquired the kinds of reasoning biases that seem to make them depart from the canons of probability theory. Given the incompleteness of our knowledge of even recent human history, evolutionary approaches remain necessarily speculative. However, advances in genetics and bioinformatics may broaden the interdisciplinary range still further. But before considering current directions in cognitive science, it is worth sketching some history.

The Rise of Cognitivism

In the 19th century, researchers such as Hermann von Helmholtz and Hermann Ebbinghaus studied human thought and developed systematic methods for measuring relevant processes, such as the conduction of nerve signals, or the rate of forgetting. Others, such as Wilhelm Wundt, maintained that controlled introspection could also deliver useful insights into the workings of people's minds. However, in the late 19th and early 20th centuries, introspection fell into disrepute. It took with it most theories involving 'unobservable' mental entities, whether they had been objectively observed or not. It is true that the cognitive tradition did continue, thanks to Russian researchers such as Alexander Luria and Lev Vygotskii. But in North America and most of Europe, the behaviorist school, led by researchers such as John Watson, Edward Thorndike, and B. F. Skinner, argued that the only proper objects of psychological study were the externally observable stimuli and responses of humans and other animals.

In the mid- to late 20th century, behaviorism fell from favor. One reason was the perception that – although it had developed some sophisticated experimental methods, such as various forms of conditioning for studying learning – it was not actually delivering useful psychological generalizations. Another reason was that it came under heavy attack: Noam Chomsky (1959), for example, argued that skilled behavior – linguistic behavior in particular – required mediating mental entities to explain it. Behaviorism might still have survived, but by then there was a respectable alternative.

The alternative arose from the invention, during World War II, of computers. Alan Turing's prewar mathematical and metamathematical work had laid the theoretical foundations for modern computing. According to (one formulation of) the thesis of the American mathematician Alonzo Church, all computable functions are Turing computable; what are now known as 'Turing machines' are theoretical devices for effectively computing mathematical functions. During the war, actual computing machines were built for code-breaking purposes and for other numerically intensive calculations; Turing was instrumental in this effort in the United Kingdom, along with John von Neumann in the United States. After the war, Turing (1950) laid out a vision of machine (or artificial) intelligence. It maintained that what mattered for attributing intelligence to an unknown agent was (as before) its observable behavior; it would be considered intelligent if it passed what subsequently became known as the 'Turing test.' But now, this behavior could be generated by a machine that transformed input data into output data by following an internally stored algorithm.

These ideas gave birth to the fields of computer science and artificial intelligence, the latter of which was nurtured by, among others, John McCarthy and Marvin Minsky, who proposed an artificial intelligence summer project for 1956 at Dartmouth College, New Hampshire. Turing's ideas also had a huge impact in the philosophy of mind, a growing influence in psychology, and soon led to significant interactions between linguistics and computer science (Chomsky,

1957). Turing machines had a relatively simple architecture, but alternative ways of designing computers were soon being developed. von Neumann's architecture was slightly more complex: a single central processor consulted a special part of the computer's memory to find which program instruction to carry out next; on the basis of the instruction, it manipulated other parts of its memory, which were dedicated to storing data. At about the same time, McCulloch and Pitts (1943) developed a very different computer architecture, inspired by the relations between neurons in brains: rather than a single (powerful) processor, with access to large amounts of program and data memory, they perceived that a useful computer can be composed of a large number of rather simple processors with small amounts of memory, so long as the processing nodes are properly interconnected; simple rules could be followed for updating the nodal states, on the basis of the neighboring states.

The von Neumann machine architecture dominated both computer science and cognitive science for decades. As a result, researchers focused on the types of representations that were naturally manipulated within this kind of architecture. Whereas, at low levels, computers might store information in binary digital form, they could be programmed to interpret and generate sequences of symbols. The logical roots of computing reach back at least to Gottlob Frege (1848–1945), and the language and logic of first-order predicate calculus came to function as a symbolic lingua franca for many researchers, providing models for both language and reason.

The idea that computers could run programs that led to intelligent behavior was a special gift to philosophers, such as Hilary Putnam. Computers appear to furnish solutions to a number of crucial problems, including the mind–body problem and the homunculus problem. The mind–body problem concerns the relation between mental states and events and bodily states and events. For instance, are all mental events really just physical events, differently described? Is there a special kind of mental substance? If so, how does it interact with physical substances? The homunculus problem concerns the relation between mental representations and the minds that contain them. If my representation of a pig is a mental image of a pig, who looks at the mental image? Traditionally, it was suggested that the mind would have to contain a viewer who inspected the image; the 'homunculus,' or 'little man,' was needed to fulfill this role. But since the homunculus also had to contain a mental image, he also contained another homunculus. With an infinite regress threatening, the homunculus looks like a nonexplanation.

Computers appear to help solve the mind–body problem because they provide a beautiful analogy: the brain is to the mind as the computer is to the program. A program has a purely physical instantiation, because it is stored in the computer's memory. But when the program runs, interesting – sometimes even intelligent – behavior can occur. Taken further, perhaps the human brain (or the whole body containing the brain) really is just a computer, and the mind is therefore the product of programs running on the computing machine. Computers appear to solve the homunculus problem because they contain internal representations that do not need a smart little man to read them. A very complex program can be decomposed into a finite set of simple instructions. Each of those instructions can be carried out by a very simple processor of limited powers. There is no little man in the machine.

Central Issues in Cognitive Science

With the computational metaphor to empower it, the study of human psychology was liberated from the constraints of behaviorism. From the 1950s to the 1970s, information-processing models were developed to cover a range of human cognitive capacities, such as memory, attention, reasoning, and problem solving (Miller, 1956; Broadbent, 1958; Johnson-Laird and Wason, 1970; Newell and Simon, 1972).

Marr's (1982) work on vision encapsulated the strength of cognitive science, framing three key levels of explanation: the computational, algorithmic, and implementational. The first of these involves the behavior of a human agent given a specific task, the second involves the cognitive or affective systems underlying a given computational task (it is at this level that mental processes and representations are traditionally located), and the third involves the basic biological systems underlying the algorithmic level (such as the brain). Sometimes computational behavior can be explained directly in terms of implementational things and events (explanations involving localized brain damage sometimes take this form), but more frequently, the algorithmic level is required to identify common causes of computational-level behavior.

Modeling human language processing was a central goal for cognitive scientists, and in this context, a number of larger issues emerged. Jerry Fodor played an important role in bringing at least three key issues into focus. One issue concerns the nature of internal mental representations. Fodor (1975) argued that to explain human conceptual learning, we had to posit the existence of 'mentalese,' a language of thought having properties that reflected those of natural

languages. Others, such as Pylyshyn (1973), revived an old debate about the nature of mental imagery, to argue that evidence in favor of image-like mental representations could be explained purely in terms of language-like mental representation. Most recently, however, the pendulum has swung in the opposite direction, and many researchers are now pursuing the idea that language processing draws on mental representations that have imagistic (perceptually oriented) components and motoric (action-oriented) components (Pulvermüller, 1999).

A second issue concerns the relationships between our various mental capacities. Fodor (1983) revisited the notion of faculty psychology, arguing that the human mind is modular in nature, with relatively limited communication between specialized modules. Language processing, in particular, was taken to involve modules that operated automatically, very different in kind from the operation of central (conscious) reasoning. Ideas about the extent and origin of modularity of mind have been very influential and are related to the nativist/empiricist debate (Pinker, 1994; Elman *et al.*, 1996). Modularity has been adopted by evolutionary psychologists such as Leda Cosmides. The massive modularity hypothesis suggests that the mind is highly modularized and that the domain-specific modules correspond to evolutionary adaptations, acquired by our ancestors in solving persistent problems in the relatively recent past. Although these modules may be adaptations, they may not remain adaptive, and this constitutes part of the explanation as to why humans do not always reason in accordance with the canons of probability theory. Evolutionary psychology has its problems, however, not the least of which is the paucity of data concerning the environment of evolutionary adaptation. In the face of this, alternative explanations for apparent anomalies in human reasoning are still being developed, some of which draw explicitly on the idea that reasoning and language interpretation are intimately intertwined (Stenning and van Lambalgen, 2004).

A third and final issue concerns the computational architecture underlying the human mind. Although the von Neumann architecture has prevailed in computer science and cognitive science, the neural architecture proposed by McCulloch and Pitts ran a more checkered career. The neural architecture lends itself very naturally to learning how to compute functions that transform stimuli into responses. Turing had emphasized that for practical purposes, an intelligent machine would have to be a learning machine. But results from Marvin Minsky and Seymour Papert in the 1960s suggested that there were fundamental limits to what neutrally inspired perceptrons could learn to compute. It was not until the early 1980s that work by David Rumelhart and James McClelland and collaborators revived the approach, under the banner of 'parallel distributed processing,' or more generally, 'neo-connectionism.' The development of effective learning algorithms allowed connectionist machines to alter the strengths of connections between nodes, either with or without supervision from outside, and to accomplish a much broader range of computational tasks. The distinction between traditional and neural architectures is sometimes drawn in terms of the representations used by the machines. As already noted, traditional architectures usually store (at least some) information about the world in sentence-like symbolic structures, composed of symbols representing real-world entities and the relations between them. By contrast, connectionist architectures are sometimes considered nonsymbolic or subsymbolic: in some systems, processing nodes may correspond directly to specific real-world entities; but in distributed representation systems in particular, a given node may participate in representing many different real-world objects or relations, and representing a given object may require the activation of many processing nodes.

There has been a vast amount of subsequent work on connectionist modeling of human cognitive tasks. The models have two special virtues: unlike symbolic approaches, learning is built in. This is good, because learning is core to many cognitive abilities. And unlike symbolic approaches, damaging a network leaves residual function. This means that is possible to simulate the effects of lesions in the brain. Many successful models do just this, such as the models of dyslexia by Plaut and Shallice (1994). On the other hand, there are some things that symbolic systems do better than neural systems. For instance, certain properties of language, such as constituency and recursion, are taken to be dealt with quite naturally by symbolic systems, but to pose problems for connectionist systems (Fodor and Pylyshyn, 1988). Considerable effort has consequently been devoted to showing that connectionist systems can indeed process languages with such properties. It has also been argued that connectionist systems are better models of humans because neural networks are more similar to brains than von Neumann architectures are. Against this, neural networks abstract away from many (in fact, nearly all) features of real brain circuitry, and many of the learning algorithms used are biologically implausible. On the other hand, some algorithms are indeed deliberately modeled on processes in neural circuits, such as Hebbian reinforcement (Hebb, 1949).

Current Directions

The past decade has seen an explosion in the number of studies that use at least one brain imaging technique. These include positron emission tomography, functional magnetic resonance imaging, and transcranial magnetic stimulation. The last of these goes beyond straightforward (but computationally intensive) imaging and actively alters brain states in experimental participants (for an introduction to work relevant to language, see, for instance, Poeppel and Hickok (2004)). Cognitive neuroscience started from an interest in pathologies, such as blindsight, but imaging technologies have progressed to the point where many studies are carried out on normal individuals executing simple cognitive tasks. As a result, there is a popular conception that cognitive science is brain science. But, given Marr's three levels of explanation, implementation in brains is only part of the overall picture, and, equally, it is perfectly possible to study the brain without being interested in cognitive processes. What cognitive studies bring to brain science is the ability to demarcate a coherent set of cognitive capacities, and it is these that can (sometimes) be localized within particular brain areas.

Imaging is also, at least in part, responsible for the rehabilitation in recent years of the study of consciousness and emotion. New measurement technologies allow even those researchers who are suspicious of subjective or introspective reports to begin to investigate empirically brain states and events associated with consciousness. The study of emotion and other affective states has also progressed considerably, allowing interactions between affective and cognitive processes to be traced with increasing precision (Davidson and Irwin, 1999). The rapprochement between affect and cognition is particularly notable; for instance, new work on personality and individual differences takes account of imaging results in explicitly advocating cognitive models of personality traits such as anxiety (Matthews *et al.*, 2000).

Another line of development generalizes from one aspect of connectionism: learning from data. The increasing availability of online corpora (of images, speech, and text) has encouraged researchers to explore how far statistical learning techniques can model cognitive performance in real-world domains. From an engineering point of view, substantial successes have been achieved. For instance, both speech processing and, more recently, text processing have been revolutionized by the recruitment of statistical techniques. These successes are mirrored by developments in cognitive science, in language processing, and beyond. On the language side, approaches such as latent semantic analysis have been developed to form the basis of psychological theories of textual meaning (Landauer and Dumais, 1997). More generally, the rational analysis of cognition proposes that a cognitive system operates as a probabilistic engine, to optimize the adaptation of the organism's behavior to its environment (Anderson, 1990; Chater and Oaksford, 1999).

A final area of burgeoning interest arises from progress in genetic research enabled by developments in bioinformatics. Most researchers do not expect to find a one-to-one mapping from genes to specific cognitive capacities or dispositions. Thus, the idea that there might be a single 'language gene' is increasingly considered unsophisticated. However, as genealogy, molecular biology, behavioral genetics, and language research are brought together, significant results are already beginning to emerge. In 2001, *FOXP2* was isolated as a gene in which a point mutation correlates with language (and other) disorders in affected members of the intensively studied three-generation KE family (Lai *et al.*, 2001). The gene codes for a transcription factor, and changes in its structure may therefore have a broad effect on the expression of genes during cognitive development. As might be expected, imaging techniques have also been brought to bear on the KE family (Liégeois *et al.*, 2003), but for current purposes, this recent progress on *FOXP2* is merely the harbinger of changes to come.

Cognitive science has always had the computational metaphor at its core. But with increasingly sophisticated hardware, ever larger online corpora, and more powerful software for processing that data, it seems that computational power is more important than ever for future progress in the interdisciplinary scientific study of the mind.

Cognitive Linguistics and Cognitive Semantics

Cognitive semantics is part of a wider movement known as 'cognitive linguistics.' Prior to surveying the main characteristics of cognitive semantics, it will be advisable to clarify what is meant by cognitive linguistics. As a matter of fact, the term is open to different interpretations. On a broad understanding, any approach that views language as residing in the minds of its speakers and a linguistic description as a hypothesis about a speaker's mental state would merit the designation 'cognitive.' Chomsky's career has been devoted to pursuing cognitive linguistics on this broad understanding. On the narrower, and more specialized interpretation intended here, cognitive linguistics refers to a movement that emerged in the late 1970s and early 1980s, mainly as a reaction to certain tendencies of Chomskyan, and, more generally, formalist linguistics. Linguists who were prominently associated with the emergence of cognitive linguistics, in this narrow sense, were George Lakoff, Ronald Langacker, and Leonard Talmy.

Rather than a specific theory, cognitive linguistics can best be described as an approach, or cluster of approaches to language study, whose practitioners nevertheless share a basic outlook on the nature of language. Several common aspects can be identified:

- Cognitive linguists are skeptical of the idea, promoted within Chomskyan linguistics, that human language might be associated with a language-specific module of the mind. Their starting point, rather, is that language is embedded in more general cognitive abilities and processes. According to the editorial statement of the monograph series *Cognitive linguistics research* (published by Mouton de Gruyter, Berlin), the guiding assumption is that 'language is an integral facet of cognition which reflects the interaction of social, cultural, psychological, communicative and functional considerations, and which can only be understood in the context of a realistic view of acquisition, cognitive development and mental processing.' Special attention, therefore, has been directed towards studying language, its structure, acquisition, and use, from the perspective of such topics as perception, categorization, concept formation, spatial cognition, and imagery. Although these capacities might well be subject to highly specialized elaboration in human language, they are not *per se* linguistic capacities.
- Cognitive linguistics signaled a return to the basic Saussurean insight that language is a symbolic system, which relates signifiers (that is, language in its perceptible form, whether as sound, marks on paper, or gesture) and signifieds (that is, meanings). Indeed, Langacker (1987: 11) characterized a language as 'an open-ended set of linguistic signs [. . .], each of which associates a semantic representation of some kind with a phonological representation.' Importantly, semantic representations, i.e., 'meanings,' are taken to be mental entities, or, perhaps more appropriately, mental processes. Thus, Langacker prefers to refer not to 'concepts' (a term that suggests that meanings are static, clearly individuated entities) but to 'conceptualizations,' where the deverbal nominal emphasizes the dynamic, processual character of the phenomenon.
- A third feature of cognitive linguistics follows from the view of language as a symbolic system, namely that syntax and morphology – patterns for the combination of words and morphemes into larger configurations – are themselves symbolic, and hence inherently meaningful. The same goes for the elements over which syntax and morphology operate – lexical and phrasal categories, for example – as well as the kinds of relations that can hold between these elements, i.e., relations such as subject (of a clause), modification, complementation, apposition, subordination. The view, current in many linguistic theories, that syntax and morphology constitute autonomous levels of linguistic organization is therefore rejected. Indeed, a major thrust of cognitive linguistic research over the past couple of decades has been, precisely, the attempt to offer a conceptual characterization of formal aspects of language organization.

It will be apparent that the orientation of cognitive linguistics, as characterized above, was bound to have considerable influence on the ways in which meanings (whether of words, sentences, syntactic patterns, etc.) have been studied. One aspect has already been mentioned, namely, that meanings are taken to be mental entities. In this, cognitive linguistics contrasts strikingly with other approaches, such as logical approaches, which have focused on logical aspects of sentences and the propositions they express; with truth-conditional approaches, which focus on the relation between propositions and states of affairs in the world; with structuralist approaches, which view meaning in terms of semantic relations within the

language; with behaviorist approaches, which view meaning in terms of stimulus-response associations; and, more generally, with theories of meaning as use. What these alternative approaches to meaning have in common is their avoidance of mentalism, i.e., the characterization of meanings as 'things in the head.'

The remainder of this article surveys some important themes and research topics in cognitive semantics. It should be mentioned that the survey is by no means comprehensive; for broader coverage, the reader is referred to the introductions to cognitive linguistics listed at the end of this article. Some topics, such as metaphor and metonymy, are dealt with elsewhere in this encyclopedia and for this reason are discussed only briefly. It should also be borne in mind that cognitive semantics, like cognitive linguistics itself, does not constitute a unified theory, but is better regarded as a cluster of approaches and research themes that nevertheless share a common outlook and set of assumptions.

Meaning Is Encyclopedic in Scope

Many semanticists, especially those who see the language faculty as an encapsulated module of the mind, insist on the need to make a distinction between the dictionary and the encyclopedia, that is, between what one knows in virtue of one's knowledge of a language and what one knows in virtue of one's knowledge of the world. Cognitive semantics denies the validity of such a distinction. On the contrary, meaning is taken to be essentially encyclopedic in scope. A person's linguistic knowledge would therefore, in principle, be coextensive with the person's total world knowledge. An individual word, to be sure, provides access to only a small segment of encyclopedic knowledge. No clear bounds, however, can be set on how far the relevant knowledge network extends.

The encyclopedic nature of linguistic semantics is captured in the notions of profile, base, domain, and Idealized Cognitive Model (or ICM).

The terms 'profile' and 'base' are due to Langacker (1987). A linguistic expression intrinsically evokes a knowledge structure, some facet of which is profiled. Take the word *hypotenuse*. The word designates a straight line. Whatever we predicate of *hypotenuse* is predicated of a hypotenuse *qua* straight line, as when we assert *The hypotenuse is 3 cm. long*. Obviously, the notion of a straight line does not exhaust the meaning of the word. The straight line in question is part of a larger structure, namely, a right-angled triangle. Although *hypotenuse* does not designate the triangle, the notion of a triangle is essential for the understanding of the word (Figure 1). Notice that

Figure 1 Notion of hypotenuse.

the concept designated by the word cannot be identified with the profile – as mentioned, the profile is simply a straight line. The concept resides in the profiling of a facet of the base.

For other examples that illustrate the profile-base relation, consider words such as *thumb* (profiled against the conception of a human hand), *top* (profiled against a schematic notion of a three-dimensional entity), *island* (a mass of land profiled against the surrounding water). In fact, it is axiomatic, in cognitive semantics, that all expressions achieve their meaning through profiling against the relevant background knowledge.

Returning to the hypotenuse example, it will be apparent that the base – the notion of a triangle – itself presupposes broader knowledge configurations, namely, those pertaining to planar geometry, which themselves are based in notions of space and shape. These broader knowledge configurations are referred to as 'domains.' Some domains may be basic, in the sense that they are not reducible to other domains. Examples include time, space, color, temperature, weight, etc. Otherwise, a knowledge structure of any degree of complexity can function as a domain, for example, the rules of a game, a scientific theory, kinship networks, gender stereotypes, educational, political, and legal systems. Domains may also be constituted by deeply held beliefs about life, nature, causation, the supernatural, and so on.

Most concepts are characterized against a 'matrix' of more than one domain. *Uncle*, for example, profiles a male human being against the base of a (portion of a) kinship network, specifically, that part of the network that relates the uncle to his nephews/nieces. The notion of kinship itself rests on notions of gender, procreation, marriage, inheritance, etc. At the same time, *uncle* profiles a human being, which is understood against multiple domains pertaining to

life forms, to three-dimensional bodies and their various parts, with their features of weight, extension, shape, and so on. If we add to this the fact that, in many societies, uncles may have special rights and obligations *vis-à-vis* their nephews/nieces, we may appreciate that even a single word, if its meaning is fully explored, can take us into the farthest reaches of our knowledge and cultural beliefs.

It will be apparent that the distinction between base and domain is not a clear-cut one. The base may be defined as a knowledge structure that is inherently involved in profiling, whereas domains constitute background, more generalized knowledge. Terminology in this area is also confusing because different authors have favored a range of terms for domain-based knowledge. Some scholars have used the not always clearly distinguishable terms 'scene,' 'scenario,' 'script,' and 'frame' to refer in particular to knowledge about expected sequences of events. Thus, *anger* refers not just to an emotional state, but is understood against an expected scenario that includes such stages as provocation, response, attempts at control, likely outcomes, and so on. Likewise, paying the restaurant bill evokes the 'restaurant script' – knowledge of the kinds of things one does, and the things that happen, when one visits culturally instituted establishments known as 'restaurants.' The notion of paying also invokes the frame of a commercial transaction, with its various participants, conventions, and activities. Mention might also be made of Searle's (1992) notions of 'the Network' and 'the Background,' whereby a particular belief takes its place within a network of other beliefs, and against the background of capacities, abilities, and general know-how.

Of special importance is Lakoff's (1987) notion of 'Idealized Cognitive Model,' or ICM – a notion that bears some affinity with the concept of 'folk theory' (again, different scholars prefer different terms). ICMs capture the fact that knowledge about a particular domain may be to some extent idealized and may not fit the actual states of affairs that we encounter on specific occasions. Consider the words *bachelor* and *spinster*. We might define these as 'adult unmarried male' and 'adult unmarried female,' respectively. The concepts, thus defined, presuppose an ICM of marriage practices in our society. According to the ICM, a person reaches a more-or-less clearly definable marriageable age. People who pass the marriageable age without marrying are referred to as bachelors and spinsters, as the case may be. The ICM attributes different motives to men and women who do not marry. Men do so out of choice, women out of necessity. As will be appreciated, the ICM is idealized, in that it presupposes that all citizens are heterosexual and that all are equally available for marriage. It thus ignores the existence of celibate priests and of couples who live together without marrying. The discrepancy between model and reality can give rise to prototype effects. The fact that the Pope is not a representative example of the bachelor category derives from the fact that Catholic clergy are not covered by the ICM. Appeal to the ICM can also explain the different connotations of *bachelor* and *spinster*. Although one might not want to subscribe to the sexist framing of the ICM, it does offer an explanation for why *eligible bachelor* is an accepted collocation, whereas *eligible spinster* is not.

As mentioned, the meaning of a word may need to be characterized against a matrix of several domains. However, not all uses of a word need invoke each of the domains in equal measure. Certain uses may activate only some domains whereas others are backgrounded or eclipsed. The notion of a kinship network is likely to be prominent in most uses of *uncle*, yet when parents use the word to introduce one of their adult male friends to their child, the kinship domain is eclipsed. For another example of selective domain activation, consider the concept of a book. When you *drop a book*, the status of the book as a (heavy) material object is activated, when you *read a book*, the status of a book as a printed text is activated, when you *translate a book*, the status of the book as a text in a given language is foregrounded. Note that *begin a book* can be interpreted in various ways, according to which of the domains is activated. The activity that one begins with respect to the book could be reading, writing, editing, translating, or even (if you are bookworm, literally!), eating.

The above examples not only illustrate the importance of domains and related notions in the study of word meanings, they also show why it has been deemed necessary to favor an encyclopedic approach to semantics. The reason is, namely, that we need to appeal to domain-based knowledge in order to account for how words are used and for the ways in which complex expressions are judged. Often, the very possibility of interpreting an expression, and of accepting it as semantically well-formed, can only be explained by reference to appropriate background knowledge.

A common objection to an encyclopedic semantics is that one cannot reasonably claim that everything a person knows about the concept designated by a word is relevant to the use of the word. It is certainly true that some facets of background knowledge may be central, and more intrinsic to a concept, others might be more peripheral or even idiosyncratic to an individual speaker. Nevertheless, even extrinsic knowledge might become relevant to a word's use,

for example, in discourse between intimates or family members. Moreover, the study of semantic change teaches us that even highly peripheral and circumstantial knowledge pertaining to a concept can sometimes leave its mark on the semantic development of a word. Langacker (1987: 160) has remarked that Jimmy Carter's presidency had a notable, if transient, effect on the semantics of *peanut*. Equally, Margaret Thatcher's premiership probably influenced the semantic development of *handbag*, at least for British speakers.

The notion of domain is relevant to two important themes in cognitive semantic research, namely metaphor and metonymy. 'Metaphor' has been analyzed in terms of the structuring of one domain of experience (usually, a more abstract, intangible domain) in terms of a more concrete, and more directly experienced domain. For example, time is commonly conceptualized in terms of space and motion, as when we speak of *a long time*, or say that Christmas *is approaching*, or even that it *is just around the corner*. More recently, metaphor has been studied under the more general rubric of 'conceptual blending,' whereby components of two or more input domains are incorporated into a new conceptualization, the blend. Whereas metaphor involves elements from more than one domain, 'metonymy,' in contrast, concerns elements within a single domain. Thus, we can use the name of an author to refer to books written by the author, as when we enquire whether someone *has read any Dickens*. The transfer of reference from person to product is possible because both are linked within domain-based knowledge pertaining to books and their authorship.

Categorization

Every situation and every entity that we encounter is uniquely different from every other. In order to be able to function in our physical and social worlds, we need to reduce this information overload. We do this by regarding some situations and some entities as being essentially 'the same.' Having categorized an entity in a certain way, we know how we should behave towards it and what properties it is likely to have. It is significant that whenever we encounter something whose categorization is unclear we typically feel uneasy. 'What is it?', we want to know.

Categorization is not a peculiarly human ability. Any creature, if it is to survive, needs at the very least to categorize its environment in terms of edible or inedible, harmful or benign. Humans have developed phenomenal categorization abilities. We operate with literally thousands, if not hundreds of thousands of categories. Moreover, our categories are flexible enough to accommodate new experiences, and we are able to create new categories as the need arises.

To know a word is to know, among other things, the range of entities and situations to which the word can be appropriately applied. To this extent, the study of word meanings is the study of the categories that these words denote. And it is not only words that can be said to designate categories. It can be argued that syntactic configurations, for example, those associated with intransitive, transitive, and ditransitive constructions, designate distinct categorizations of events and their participants.

What is the basis for categorization? Intuitively, we might want to say that things get placed in the same category because of their similarity. Similarity, however, is a slippery notion. One approach would be to define similarity in terms of the sharing of some common feature(s) or attribute(s). Similarity, then, would reduce to a matter of partial identity. Feature-based theories of categorization often require that all members of a category share all the relevant features. A corollary of this approach is that categories are well-defined, that is, it is a clear-cut matter whether a given entity does, or does not, belong in the category. It also follows that all members have equal status within the category.

There are a number of problems associated with this approach. One is that the categories designated by linguistic expressions may exhibit a prototype structure. Some members of the category might be more representative than others, while the boundary of the category may not be clearly defined. In a well-known passage, though without introducing the prototype concept, Wittgenstein (1953: §66) drew attention to categorization by family resemblance. Imagine a family photograph. Some members of the family might have the family nose, others might have the family chin, others might have the family buck teeth. No member of the family need exhibit all the family traits, yet each exhibits at least one; moreover, some members might exhibit different traits from others. Wittgenstein illustrated the notion on the example of the kinds of things we call 'games,' or *Spiele* (Wittgenstein was writing in German). Some (but not all) games are 'amusing,' some require skill, some involve luck, some involve competition and have winners and losers. The family resemblance notion has been usefully applied to the study of word meaning. Thus, some uses of *climb* (as in *The plane climbed to 30 000 feet*) exhibit the feature 'ascend,' some (such as *The mountaineers climbed along the cliff*) exhibit the feature 'move laboriously using one's limbs.' Considered by themselves, these two uses have very little in common. We see the relation, however, when we

consider some further uses of *climb* (as in *The boy climbed the tree*), which exhibit both of the features.

A fundamental problem with feature-based theories of categorization concerns the nature of the features themselves. As Wittgenstein pointed out, skill in chess is not the same as skill in tennis. The concept of skill therefore raises the very same issues of how categories are to be defined as were raised by the notion of game, which the notion of skill is supposed to explicate. Understanding similarity in terms of partial identity is problematic for another reason. Practically any two objects can be regarded as similar in some respect (for example, both may weigh less than 100 kg., or both may cost between $5 and $5000), but this similarity does not mean that they constitute a viable or useful category. An alternative approach would be that categorization is driven by the role of the entities within broader knowledge configurations, that is, by domain-based knowledge and ICMs. Sometimes, apparently similar activities might be categorized differently, as when making marks on paper might be called, in some cases, 'writing', in other cases, 'drawing.' The distinction is based on knowledge pertaining to the nature and purpose of 'writing' and 'drawing.' On the other hand, seemingly very different activities might be brought under the same category. In terms of the actions performed, making marks with a pen on a piece of paper has little in common with depressing small, square-shaped pads on a keyboard. But given the appropriate domain-based knowledge, both can be regarded as instances of 'writing.' Categories, as Murphy and Medin (1985) have aptly remarked, are ultimately based in 'theories' (that is, in ICMs).

The matter may be illustrated by the distinction (admittedly, not always a clear-cut one) between 'natural kinds' and 'nominal kinds.' Natural kinds are believed to be given by nature and are presumed to have a defining 'essence'; moreover, we are inclined to defer to the scientists for an elucidation of their defining essence. Nominal kinds, in contrast, are often defined *vis-à-vis* human concerns, and their perceptual properties and/or their function is often paramount in their categorization. Remarkably, even very young children are sensitive to the difference (Keil, 1989). Suppose a zebra had its stripes painted out; would it thereby become a horse? Or suppose a giraffe had its neck surgically shortened; would it cease to be a giraffe? Even very young children respond: 'No.' Changes to the appearance of the entities would not alter their defining essence. But suppose you saw off the back of a chair. Does the chair become a stool? Arguably, it does. In this case, a 'superficial' aspect is crucial to categorization.

The dynamics of categorization may be illustrated by considering the relationship between a linguistic expression (e.g., the word *fruit*) and its possible referents (e.g., an apple). We can address the relation from two perspectives. We can ask, for this word, what are the things in the world to which the word can be applied? Alternatively, we can ask, for this thing, what are the linguistic expressions that can refer to it? The first perspective (the 'referential' perspective: 'To what does this word apply?') operationalizes the notion of prototype. *Fruit* designates, primarily, such things as apples, pears, and bananas – these are the fruit prototypes. Less commonly, the word might be used to refer to olives and tomatoes. The second perspective (the 'onomasiological,' or naming perspective: 'What is this thing to be called?') operationalizes the notion of basic level. It is evident that one and the same thing can be named by terms that differ in their specificity vs. generality. For example, the thing you are now sitting on might be called a *chair*, an *office chair*, a *piece of furniture*, an *artifact*, or even a *thing*. All of these designations could be equally 'correct.' Yet, in the absence of special reasons to the contrary, you would probably call the thing a *chair*. (This, for example, is probably the answer you would give if a foreign learner wanted to know what the thing is called in English.) *Chair* is a basic level term, the basic level being the level in a taxonomy at which things are normally named. The basic level has this special status because categorization at this level provides maximum information about an entity. Thus, at the basic level, chairs contrast with tables, beds, and cupboards – very different kinds of things, in terms of their appearance, use, and function. Terms at a lower level in a taxonomy, e.g., *kitchen chair* vs. *office chair*, do not exhibit such a sharp contrast while terms at a higher level are too general to give much information at all about an entity. Not surprisingly, basic level terms turn out to be of frequent use, they are generally quite short and morphologically simple, and they are learned early in language acquisition.

The Usage-Basis of Cognitive Semantics

Langacker has described cognitive linguistics as a 'usage-based' approach. The claim can be understood in two ways. On the one hand, it could be a statement about the methodology of cognitive linguistic research. Usage-based research would be research based on authentic data, as documented in a corpus, recorded in the field, or elicited in controlled situations, rather than on invented, constructed data. Although different researchers might prefer different

methodologies, a glance at practically any publication by leading figures in the field, such as Lakoff, Langacker, and Talmy, will show that cognitive linguistics, as a movement, cannot reasonably be said to be 'usage-based' in this sense.

On a second interpretation, usage-based refers to the presumed nature of linguistic knowledge and the manner in which it is acquired, mentally represented, and accessed. The claim, namely, is that a language is learned 'bottom-up' through exposure to usage events. A usage event presents the language user/learner with an actual vocalization in association with a fine-grained, context-dependent conceptualization. Acquisition proceeds through generalization over usage events. Necessarily, many of the context-dependent particularities of the usage events will be filtered out, leaving only a schematic representation of both the phonology and the semantics. In this respect, cognitive linguistics contrasts strikingly with 'top-down' theories of acquisition, whereby the basic 'architecture' of a language is presumed to be genetically given, exposure to usage data being needed merely to trigger the appropriate settings of innately given parameters.

The usage-based approach raises two questions, which have loomed large in cognitive semantics research. These concern (a) the units over which schematization occurs, and (b) the extent of schematization. Let us first consider the second of these issues.

One of the most vibrant areas of cognitive semantic research has been the study of lexical polysemy. It is a common observation that words exhibit a range of different meanings according to the contexts in which they are used. Indeed, the extent of polysemy appears to be roughly proportional to the frequency with which a word is used. Not surprisingly, among the most highly polysemous words in English are the prepositions.

Consider the preposition *on*. Given such uses as *the book on the table* and *the cat on the mat*, it is easy to see how a schematic, de-contextualized image of the *on*-relation could emerge. It involves locating one object with respect to another in terms of such aspects as contact, verticality, and support. But the preposition has many other uses, as exemplified by *the fly on the ceiling*, *the picture on the wall*, *the leaves on the tree*, *the writing on the blackboard*, *the washing on the clothes-line*, *the shoes on my feet*, *the ring on my finger*. Do we proceed with further abstraction and schematization, coming up with a characterization of the *on*-relation that is compatible with all of these uses? Or do we identify a set of discrete meanings, which we may then attempt to relate in a prototype or a family resemblance category? If we adopt this latter approach, another question arises, namely, just how many distinct meanings are to be postulated. Three? Ten? Several dozen? Do we want to say that *the water on the floor* and *the cat on the mat* exemplify different senses of *on*, on the grounds that the relation between *cat* and *mat* is not quite the same as that between *the water* and *the floor*? Needless to say, the issue becomes even more critical when we take into consideration the vast range of nonspatial uses of the preposition: *on television*, *be on a diet*, *be on drugs*, *on Monday*, and countless more.

In general, as is consistent with a usage-based orientation, cognitive semanticists have tended to focus on the particularities of low-level generalizations, an approach that has frequently been censured for the 'polysemy explosion' that it engenders. Nevertheless, the role of more schematic representations is not denied. Langacker, in this connection, draws attention to the 'rule-list fallacy.' The fallacy resides in the notion that rules (high-level generalizations), once acquired, necessarily expunge knowledge of the lower-level generalizations on whose basis the rules have been abstracted. It is entirely plausible that high- and low-level generalizations might co-exist in the mental grammar.

Indeed, knowledge of low-level generalizations – not too far removed, in terms of their schematicity, from actually encountered usage-events – may be needed in order to account for speakers' fluency in their language. The topic interacts with a more general issue, namely, the relative roles of 'computation' vs. 'storage' in language knowledge and language use. Humans are not generally very good at computation, but we are quite adept at storing and retrieving specific information. Consider arithmetical operations. We can, to be sure, compute the product of 12 by 12 by applying general rules, but the process is slow and laborious and subject to error, and some people may need the help of pencil and paper. It is far easier, quicker, and more reliable to access the ready-made solution, if we have learned it, namely, that $12 \times 12 = 144$. The point of the analogy is that in order for speech production and understanding to proceed smoothly and rapidly, it may well be the case that we access ready-made patterns and preformed chunks, which have been learned in their specific detail, even though these larger units could be assembled in accordance with general principles. The role of formulaic language in fluency and idiomaticity has been investigated especially by linguists engaged in corpus-based lexicography and second language acquisition research. Their findings lend support to the view that linguistic knowledge may indeed be represented at a relatively low level. We might suppose, therefore, that *the ring on my finger* is judged to be

acceptable, not because some highly schematic, underspecified sense of *on* has been contextually elaborated, nor because some rather specific sense of *on* has been selected, but simply because speakers have encountered, and learned, such an expression.

These considerations lead into the second aspect of a usage-based model: what are the units over which schematization takes place? The study of lexical semantics has typically been based on the assumption that schematization takes place over word-sized units. Indeed, the above discussion was framed in terms of how many meanings the preposition *on* might have. The study of idioms and related phenomena, such as collocations, constructions, and formulaic expressions, casts doubt on the validity of this assumption. Corpus-based studies, in particular, have drawn attention to the fact that words may need to be characterized in terms of the constructions in which they occur, conversely, that constructions need to be characterized in terms of the words that are eligible to occur in them. It might be inappropriate, therefore, to speak of the 'mental lexicon,' understood as a list of words with their phonological and semantic properties. A more appropriate concept might be the 'mental phrasicon,' or the 'mental contructicon.' It would certainly be consistent with a usage-based model to assume that language is represented as schematizations over the units in terms of which language is encountered – not individual words as such, but phrases, constructions, and even utterance-length units.

Construal

Linguistic meaning has often been approached in terms of the correspondence between an expression and the situation that it designates. Given the expression *The cat is on the mat*, and a situation in which there is a mat with a cat on it, we might be inclined to say that the linguistic expression fully and accurately describes the observed situation. The matter, however, is not so straightforward. For any conceived situation, certain facets will have been ignored for the purpose of its linguistic expression. Where was the mat? How big was it? What color was it? Was it laid out flat or was it rolled up? Was the cat in the center of the mat? Was the cat sitting or lying? And so on. Secondly, the speaker is able to categorize the situation at different levels of schematicity. Instead of saying that *the cat is on the mat*, the speaker could have stated that *the animal is sprawled out on my new purchase*. The speaker's decision to include or exclude certain facets of the scene, and to categorize the scene and its participants in a certain way, are symptomatic of the broader phenomenon of 'construal,' namely, the way in which a conceived situation is mentally structured for the purpose of its linguistic expression.

There is a sense in which the whole cognitive semantics enterprise is concerned with how speakers construe a conceived situation and how this construal receives linguistic expression, as a function of the conventional resources of a particular language. Some important facets are construal are discussed below.

Figure-Ground Organization

A feature of our perceptual mechanism is that a perceived scene is structured in terms of 'figure' and 'ground.' Certain aspects of a scene are likely to be especially prominent and specifically attended to, whereas others are relegated to the background context. Given the situation of the cat and the mat, we are likely to say that the cat is on the mat, rather than that the mat is under the cat. Both wordings might be equally true in terms their correspondence with the situation. Yet one would normally be preferred over the other. This preference is because we would most likely select the cat as the figure, whose location is described with respect to the mat, rather than the other way round.

Figure-ground organization is ubiquitous in perception, most obviously in visual perception, but also in other modalities. When we listen to a lecture, the speaker's voice is (hopefully) the auditory figure, which stands out against the sound of the air conditioning and of people coughing and shuffling. A number of aspects influence the figure-ground alignment. The figure, as the primary object of attention, is likely to be moveable and variable, it can act, or be acted on, independently of the ground, and it is likely to be more information-rich (for the perceiver) than the ground. Moreover, animate entities – especially if human – are likely to attract our attention as figure *vis-à-vis* inanimate entities. The ground, in contrast, is likely to be static relative to the figure, it is presupposed, and provides the context for the characterization of the figure. It must be emphasized, however, that while certain inherent features of a scene may strongly suggest a certain figure-ground alignment, we can often choose to reverse the relation. While at a lecture, we could consciously direct our attention to a background noise, relegating the speaker's voice to the ground.

Figure-ground organization is built into language at many levels. The contrast between an active clause and its passive counterpart can be understood in such terms. *The farmer shot the rabbit* presents the farmer as the figure – we are interested in what the farmer did. *The rabbit was shot (by the farmer)*

presents the rabbit as figure – we are interested in what happened to the rabbit. Note that what is at issue in these examples is not so much how the scene as such might be visually perceived, but how it is mentally organized by the speaker for its linguistic encoding. Figure-ground asymmetry is also relevant to the encoding of reciprocal relations. If A resembles B, then B obviously resembles A. Yet we would be far more likely to observe that a boy resembles his grandfather than to say that an old man resembles his grandson. We take the old man as the ground, against which the growing boy is assessed, rather than vice versa.

Force Dynamics

Another aspect of construal is illustrated by the contrast between *The ball rolled along the floor* and *The ball kept rolling along the floor.* There would be no way to differentiate these sentences in terms of objective features of the situations that they designate. Whenever the one sentence can truthfully be applied to a situation, so can the other. Yet the two sentences construe the situation differently. The difference was investigated by Talmy in terms of his notion of 'force dynamics.' We view entities as having an inherent tendency either for motion (or change) or for rest (or inaction). When entities interact, their inherent force dynamic tendencies also interact. The force of one entity may overcome, or fail to overcome the force of another, or the two forces may be in equilibrium. Typically, in a force-dynamic interaction, our attention goes on a figure entity (the agonist), whose behavior is tracked relative to an antagonist.

The ball rolled along the floor presents the motion of the ball as resulting from its inherent tendency towards motion. But if we say that *the ball* ***kept*** *rolling along the floor*, we assume a force opposing the ball's activity, which, however, was not strong enough to overcome the ball's tendency towards motion. It is the verb *keep* that introduces a force-dynamic interaction into the situation, as we construe it. It conveys that the tendency towards motion of the agonist (i.e., the ball) was able to overcome an (unnamed) opposing force. The opposing force may, of course, be explicitly stated: *The ball kept rolling, despite our attempt to halt it*. Force-dynamic interaction holds even with respect to a 'static' situation. *I kept silent* designates the continuation of a static situation. The stasis, however, results from the fact that an (unnamed) antagonist was not powerful enough to cause the situation to change.

Quite a few lexical items have an implicit force-dynamic content, such as *keep*, *prevent*, *despite*, and even *finally* and *(to) manage*. Thus, *I finally managed to start my car* not only conveys that I did start my car, but also that I had to overcome an opposing force. Force dynamics offers an interesting perspective on causation. Prototypically, causation (as expressed by verbs such as *cause* or *make*) involves the agonist (the causer) exerting force that overcomes the inactivity of antagonist. Variants of this scenario including letting and preventing. *Let* conveys that the agonist fails to engage with the antagonist, while *prevent* conveys that the agonist overcomes the disposition towards action of the antagonist. Another fruitful field of application has been in the study of modality (Sweetser, 1990). Thus, *I couldn't leave* conveys that an unnamed antagonist (whether this be another person, a law or proscription, an ethical consideration, a broken leg, or even the fact of a locked door) overcame my disposition to leave. Similarly, *I had to leave* presents my leaving as resulting from a force that overcame my disposition to remain where I was.

Objective vs. Subjective Construal

Any conceptualization involves a relation between the subject of conceptualization (the person entertaining the conceptualization) and the object of conceptualization (the situation that is conceptualized). In *The cat is on the mat*, the object of conceptualization is, obviously, the location of the cat *vis-à-vis* the mat. Although not explicitly mentioned in the sentence, the subject of conceptualization is relevant to the conceptualization in a number of ways. Firstly, the use of the definite noun phrases *the cat* and *the mat* conveys that the referents of these expressions are uniquely identifiable to the speaker, also, that the speaker expects the hearer to be able to uniquely identify the referents. (It's not just ***a*** *cat*, but ***the*** *cat*.) Also, the use of the tensed verb *is* conveys that the situation is claimed to hold at the time the speaker utters the expression. Since the speaker's role is not itself the object of conceptualization, we may say that the speaker is being construed subjectively.

Langacker has illustrated the notion of objective vs. subjective construal by means of an analogy. For persons who need to wear them, their spectacles are not usually the object of their visual experience. Spectacles function simply as an aid to the seeing process but are not themselves seen. Their role is therefore a subjective one. A person can, to be sure, take off their spectacles and visually examine them, in which case, the spectacles are viewed objectively. 'Objectification,' then, is the process whereby some facet of the subject of conceptualization becomes the object of conceptualization. 'Don't talk to your mother like that,' a woman says to her child. Here, the speaker makes herself the object of conceptualization by referring to herself in the third person. 'Subjectification,'

in contrast, is the process whereby some facet of the object of conceptualization gets to be located in the subject of conceptualization. Take, as an example, the contrast between *Jim walked over the hill* and *Jim lives over the hill*. The first sentence profiles the motion of the figure entity *vis-à-vis* the ground. The second merely designates the location of the figure. The location, however, is presented as one that lies at the end of a path that goes *over the hill*. Importantly, the path is not traced by the object of conceptualization, that is, by Jim. Rather, it is the subject of conceptualization who mentally traces the path.

Subjectification has been identified as an important component of grammaticalization. Consider the use of *(be) going to* as a marker of the future. *Ellen is going to the store* can be construed objectively – Ellen is currently engaged in the process of moving towards the store. If we continue to observe Ellen's motion, we will probably find that she ends up at the store. We can easily see how *(be) going to* is likely to take on connotations of prediction. Indeed, *Ellen is going to the store* might be interpreted in just such a way, not as a statement about Ellen's current activity, but as a prediction about the future. Similarly, *It's going to rain* and *You're going to fall* have the force of a prediction, extrapolated from the observation of current circumstances. Notice, in these examples, that in spite of the use of the verb *go*, there is no objective movement, whether literal or metaphorical, towards the future situation. Rather, it is the conceptualizer who mentally traces the future evolution of the present situation. The idea of motion, contained in the verb *go*, has been subjectified, that is, it has been located in the subject of conceptualization.

A special manifestation of subjectification is the phenomenon of 'fictive motion.' This typically involves the use of a basically dynamic expression to designate an objectively static situation. *Go*, we might say, is basically a motion verb, or, more generally, a change of state verb (*I went to the airport, The milk went sour, The lights went red*). But consider a statement that *the road goes through the mountains*. No motion is involved here – the road is merely configured in a certain way, it does not (objectively) go anywhere. The idea of motion implied by *go* can, however, be attributed to the subject of conceptualization. One mentally traces the path followed by the road through the mountains. Mental motion on the part of the conceptualizer is also invoked in reference to *the road from London to Oxford*, which, of course, could be the very same entity, objectively speaking, as *the road from Oxford to London*. Similarly, one and the same entity could be referred to, either as *the gate into the garden* or *the gate out of the garden*.

Linguistic Conventions

Although speakers may construe a situation in many alternate ways, their options are to some extent constrained by the linguistic resources available to them. The matter can be illustrated with respect to language-specific lexicalization patterns. Talmy has drawn attention to alternative ways in which a motion event can be linguistically encoded. Consider the English expression *I flew across the Atlantic*. In English (and in other Germanic languages), we prefer to encode the manner of motion by means of the verb (*fly*), the path of the motion being expressed in a prepositional phrase (*across the Atlantic*). In Romance languages, an alternative construal is preferred. Path is encoded by the verb, manner by means of an adverbial phrase: *J'ai traversé l'Atlantique en avion* 'I crossed the Atlantic by plane.' Notice that, in the French sentence, the statement of the manner of motion is optional; the French speaker does not **have** to state how the Atlantic was crossed, merely that it **was** crossed. Comparison of the ways in which speakers of different languages give linguistic expression to visually presented situations, and of the ways in which texts in one language are translated into another, supports the notion that situations tend to be construed in a manner that is compatible with the construals made available by the conventional resources of different languages (Slobin, 1996). For example, speakers of English (and Germanic languages) will tend to specify the manner of motion in much finer detail than speakers of Romance languages.

Embodiment

An important theme in cognitive semantic research has been the insight that the relation between words and the world is mediated by the language user him/herself. The language user is a physical being, with its various parts, existing in time and space, who is subject to a gravitational field, and who engages in bodily interaction with entities in the environment. Quite a number of our concepts are directly related to aspects of our bodily experience. To put the matter somewhat fancifully: if we humans were creatures with a different mode of existence, if, for example, we were gelatinous, air-born creatures, floating around in the stratosphere, it is doubtful whether we could ever have access to many of the concepts that are lexicalized in presently existing human languages. Thus, to understand the concept of what it means for an object to be heavy, we have to have experienced the sensation of holding, lifting, or trying to move, a heavy object. The notion of heavy cannot be fully explicated

in purely propositional terms, nor in terms of verbal paraphrase. A characteristic of basic level terms, in particular, is that, very often, they are understood in terms of how we would typically interact with the entities in question. Consider the concept of chair. We understand the concept, not simply in terms of what chairs look like, nor even in terms of their various parts and how they are interrelated, but in terms of what we do with our bodies with respect to them, namely, we sit on them, and they support our body weight. We have no such 'embodied' conceptualization of more schematic concepts such as 'thing' or 'artifact.' We do not understand these categories in terms of how we characteristically interact with them.

The role of bodily experiences has been elaborated in the theory of image schemas (Johnson, 1987; Lakoff, 1987). 'Image schemas' are common recurring patterns of bodily experience. Examples include notions of containment, support, balance, orientation (up/down), whole/part, motion along a path from a source to a goal, and many more. (Force dynamic interactions, discussed above, may also be understood in image schematic terms.) Take the notion of balance. We experience balance when trying to stand on one leg, when learning to ride a bicycle, or when trying to remain upright in a strong wind. The notion involves the distribution of weights around a central axis. (Balance, therefore, is understood in force-dynamic terms.) The notion can be applied to many domains of experience. We can speak of *a balanced diet*, *a balanced argument*, *a political balance of power*, and of *the balance of a picture or photograph*. One could, no doubt, analyze these expressions as examples of metaphor. This approach, however, might be to miss the embodied, nonpropositional nature of the concept. Our experience of balancing provides a primitive, experiential schema that can be instantiated in many different domains.

Compositionality

A particularly contentious issue in semantics concerns the question of compositionality. According to the compositionality principle, the properties (here: the semantic properties) of the whole can be computed from the properties of the parts and the manner of their combination. From one point of view, compositionality is a self-evident fact about human language. *The cat is on the mat* means what it does in virtue of the meanings of the component words, and the fact that the words stand in certain syntactic configurations. Speakers of English can work out what the sentence means, they do not have to have specifically learned this sentence. Unless compositionality were a feature of language, speakers would not be able to construct, and to understand, novel sentences. The very fact of linguistic creativity suggests that compositionality has got to be the case.

Not surprisingly, therefore, in many linguistic theories, the compositionality of natural languages is axiomatic, and the study of semantics is to a large extent the study of the processes of semantic composition. Cognitive linguists, however, have drawn attention to some serious problems with the notion. It is, of course, generally accepted that idioms are problematic for the compositionality principle. Indeed, idioms are commonly defined as expressions that are not compositional. The expression *spill the beans* 'inadvertently reveal confidential information' is idiomatic precisely because the expression is **not** compositional, that is, its meaning cannot be worked out on the basis of the meanings that *spill* and *beans* have elsewhere in the language.

Leaving aside obviously idiomatic expressions – which, by definition, are noncompositional in their semantics – it is remarkable that the interpretation of an expression typically goes beyond, and may even be at variance with, the information that is linguistically encoded. Langacker (1987: 279–282) discussed the example *the football under the table*. The expression is clearly not idiomatic, neither would it seem to be problematic for the compositionality principle. Take a moment, however, to visualize the described configuration. Probably, you will imagine a table standing in its canonical position, with its legs on the floor, and the football resting on the floor, approximately in the center of the polygon defined by the bottom of the table's legs. Note, however, that these specific details of the visualization were not encoded in the expression – they have been supplied on the basis of encyclopedic knowledge about tables. The purely compositional meaning of the expression has been enriched by encyclopedic knowledge. There is more to this example, however. If you think about it carefully, you will see that the enriched interpretation is in an important sense at variance with the compositional meaning. If by 'X is under Y,' we mean that X is at a place lower than the place of Y, the football, strictly speaking, is not actually **under** the table at all. The football, namely, is not at a place that is lower than the lowest part of the table. In interpreting even this seemingly unproblematic expression, we have had to go beyond, and to distort, its strictly compositional meaning.

This state of affairs is not unexpected on a usage-based model. The resources of a language – lexical, syntactic, phraseological – are abstractions over encountered uses. The meanings abstracted from previous usage events are necessarily schematic, and may not fit precisely the requirements of the situation at

hand. In giving linguistic expression to a conceptualization, we search for the linguistic resources that most closely match our intentions, accepting that some discrepancies and imprecisions are likely to occur. We trust to the inferencing powers of our interlocutors to achieve the fit between the expression and the intended conceptualization.

The Conceptual Basis of Syntactic Categories

In many linguistic theories, syntax constitutes an autonomous level of organization, which mediates between phonology and semantics. As pointed out, cognitive linguistics rejects this approach. Rather, syntactic organization is itself taken to be inherently meaningful.

Several things flow from this conception of syntactic organization.

First, the notion of 'meaningless' morphemes gains little support. It is sometimes said, for example, that the preposition *of* is a dummy element in expressions such as *the destruction of the city*, inserted by the syntax in order to satisfy the constraint that a noun cannot take a noun phrase as its complement. The cognitive semantic view of the matter would be that *of* does indeed have a meaning, albeit a fairly abstract one; specifically, *of* profiles an intrinsic relation between entities. Just as talk of a *student* entails some subject matter that is studied, and talk of a *photograph* entails some thing that was photographed, so talk of *destruction* entails some entity that was destroyed. These inherent relations between entities are profiled by the same preposition: *destruction* ***of*** *the city, a student* ***of*** *physics, a photograph* ***of*** *me*.

More far-reaching, perhaps, are the implications of the cognitive linguistic approach for the study of word classes. It is almost a truism, in modern linguistics, that word classes – noun, verb, adjective, etc. – must be defined, not in semantic terms, but in terms of their distribution. The word *explosion* is a noun, not because of what it means, but because it distributes like a noun – it can take a determiner, it pluralizes, and so on. Such an approach is tantamount to claiming that syntax constitutes an autonomous level of linguistic organization, independent of semantics. Many cognitive linguists, committed to the symbolic view of language, have been skeptical of this approach and have reexamined the traditional view that word classes are indeed semantically based. There are a number of ways in which the conceptual approach can be implemented.

One is a prototype approach. Prototypically, nouns designate concrete, enduring, individuated objects, while verbs designate rapid changes of state (Givón, 1984). A problem with this approach is that *explosion*, while semantically not at all a prototypical noun, is nevertheless a noun, whose distributional properties are fully comparable with those of supposedly prototypical nouns, such as *table* and *chair*.

A second approach is functional (Croft, 1991). Nominals designate what is being talked about; adjectivals specify nominals in greater detail; verbal predications make assertions about nominals; while adverbials specify verbal predications more precisely. Each of these functionally defined categories has prototypical instances. Less prototypical instances often bear distinctive morphological markings. Thus, *explosion* betrays its nonprototypical status as an entity to be talked about by its derivational morphology.

Langacker's aim has been more ambitious. It is to offer unified conceptual definitions of the major lexical and syntactic categories. Essentially, the claim is that the syntactic category of a word is determined by the nature of its profile. Conversely, the status of a word as noun, verb, adjective, etc., imposes a certain kind of profile on the associated semantic representation.

A first distinction is between nominal vs. relational profiles. A good way to understand the distinction is by reference to autonomous vs. dependent conceptualizations. A concept is 'autonomous' if it can be entertained without necessary reference to other entities. Of course, there can be no such thing as a fully autonomous concept, given the ubiquity of domain-based knowledge and of the profile-base relation in the understanding of concepts. Nevertheless, relatively autonomous concepts can be proposed, for example, the concept of hypotenuse. As stated earlier, the word *hypotenuse* profiles a straight line. Although the concept is understood against the base of a right-angled triangle, the word does not profile the triangle, nor the relation of the hypotenuse to the triangle. It is in this sense that nominal profiles are autonomous. Compare, now, the preposition *on*. The word profiles a kind of (prototypically: spatial) relation between two entities, often referred to as the 'trajector' and the 'landmark' of the relation. The trajector can be thought of as the figure, i.e., the more prominent element in the relation, the landmark as the ground, i.e., the less prominent participant. Without some schematic notion of the trajector and landmark, the notion of 'on' lacks coherence. It is in this sense that the conceptualization associated with *on* is 'dependent' – it inherently requires reference to other entities.

Relational profiles are subject to further distinctions. *On* designates an atemporal relation – the time at which the relation holds, or over which it holds, is not profiled. Verbs, on the other hand,

Figure 2 Taxonomy of main lexical categories. Reproduced from Taylor J R (2002) *Cognitive grammar.* Oxford: Oxford University Press, with permission from Oxford University Press.

inherently designate temporal relations. *Like*, as a verb, designates a relation between a trajector (the verb's subject) and a landmark (its direct object). The temporality of the relation is a facet of the profile. Another distinction concerns the nature of the trajector and landmark. These may themselves be either nominal or relational, and, if relational, temporal or atemporal. Prepositions (*before lunch*) take a nominal landmark, subordinating conjunctions (*before we had lunch*) take as their landmark a temporal relation (i.e., a clause). Figure 2 depicts a taxonomy of the major lexical categories based on the nature of their profiles.

The combination of smaller units into larger configurations can now be understood in terms of the way in which the profiles of the smaller units can be combined. Figure 3 illustrates the assembly of *the book on the table*. (The role of the determiners is ignored so as not to unduly complicate the discussion.) In accordance with conventions established by Langacker, nominal profiles are represented by circles, relations by lines between circles, while profiled entities (whether nominal or relational) are depicted in bold. *The table*, having a nominal profile, is able to function as the landmark of *on*. The resulting expression, *on the table*, inherits the relational profile of *on*. *The book* is able to function as the trajector of this expression, whereby the resulting expression, *the book on the table*, inherits the nominal profile of *book*. The composite expression thus designates a book, the book, however, is one which is taken to be *on the table*. The pattern illustrated in Figure 3 is valid, not only for the assembly of the specific expression in question, but also, *mutatis mutandis*, for the assembly of any nominal modified by an prepositional

phrase. The pattern, therefore, is able to function as a schema that sanctions expressions of a similar internal structure.

Relativism vs. Nativism

The cognitive semantics program highlights the tension between relativism and nativism. The relativist position is that a language brings with it certain categorizations and conceptualizations of the world. The language that one speaks therefore imposes certain construals of the world. It will be evident that a number of themes in cognitive semantics are liable to emphasize the language-specific, and indeed the culture-specific character of semantic structures. For example, emphasis on the symbolic nature of language, in particular the proposal to ground syntactic categories and syntactic relations in conceptual terms, would lead one to suppose that different syntactic structures, as manifested in different languages, would be based in different conceptualizations of the

world. Equally, a focus on the role of domain-based knowledge in the characterization of meaning is likely to accentuate the culture-specific nature of linguistic semantics. On the other hand, several themes in cognitive linguistics are likely to be compatible with the nativist position, according to which the commonalities of human languages reflect a common, universal cognitive endowment. For example, the claim that language is embedded in general cognitive processes and abilities – if combined with the not unreasonable assumption that all humans share roughly the same cognitive capacities – would tend to highlight what is common to the conceptualizations symbolized in different languages. All languages, it may be presumed, manifest embodiment, image schematic and force dynamic construals, Figure-Ground asymmetries, and nominal vs. relational profiling.

Aware of the tension between relativism and nativism, Langacker has scrupulously distinguished between 'conceptual structure' and 'semantic structure.' Conceptual structure – how people perceive and cognize their world (including the inner world of the imagination) – is taken to be universal and based in shared capacities. Semantic structure, on the other hand, pertains to the way in which conceptual structure is formatted in order that it is consistent with the conventionalized resources of a given language. Compare the ways in which English and French speakers refer to bodily sensations of cold. English requires an attributive adjectival construction (*I am cold*), French require a possessive construction (*J'ai froid* 'I have cold'). Although the experience is construed differently in the two languages, one cannot on this basis alone draw the inference that English and French speakers differ in their phenomenological experience of 'being cold.'

In order to substantiate the claim that the different semantic, syntactic, and lexical resources of different languages do influence conceptualizations of the world, it would be necessary to go beyond the purely linguistic evidence and document correlations between linguistic organization and nonlinguistic cognition. Currently, the matter is hotly debated. Evidence is, however, emerging that the different construals conventionalized in different languages may sometimes have repercussions in nonlinguistic domains, giving some support to the relativist position. For example, in English (as in many other languages), we may state the location of an object by saying that it is *in front of us*, *to our left*, or *behind* another object or person. In some languages, for example, in Guugu Yimithirr (Guguyimidjir; spoken in Northern Queensland, Australia) and Tzeltal (spoken in Mexico), these resources are not available. Rather, an object's location has to be stated with respect to the cardinal points (*to the north*, etc.) or to some fixed geophysical landmark (*upstream*, *mountain-wards*). Such differences in the linguistic construal of spatial relations have been shown to correlate with nonlinguistic spatial cognition, for example, speakers' proficiency in dead-reckoning, that is, their ability to track their current location in terms of distance and direction from their home base (Levinson, 2003).

Conclusion

Meaning is central to linguistic enquiry. Meaning, after all, is what language is all about. Yet meaning is a notoriously difficult topic to analyze. What **is** meaning, and how are we to study it?

Some semanticists have studied meaning in terms of relations between language and situations in the world. Others have focused on relations within a language, explicating meanings in terms of paradigmatic relations of contrast, synonymy, hyponymy, entailment, and so on, and syntagmatic relations of collocation and co-occurrence. Yet others have tried to reduce meaning to matters of observable linguistic behavior. Cognitive semanticists have grasped the nettle and taken seriously the notion that meanings are 'in the head,' and are to be equated with the conceptualizations entertained by language users. Cognitive semantics offers the researcher a theoretical framework and a set of analytical tools for exploring this difficult issue.

Scholarly Discipline

The primary area of inquiry is Technological Cognition (TC), which examines what happens to humans when they augment themselves with technologies, either physically or cognitively, to amplify their natural capabilities. The aim of CT/TC is to formulate and to test theories of human cognitive processes that interact with technological artifacts and are partially formed by those interactions. As a fluid, symbiotic hybrid of the embodied mind and its tools, such a technologized cognition has epistemic effects: It affords an understanding and control of the external world that otherwise would not have been possible. As rational agents, humans develop and use tools to empower themselves in the *real* world which exists independently of them. This places CT/TC firmly in the realist tradition, in direct contrast with the assumptions of postmodernism (*see* **Postmodernism**): if the external world were merely a social construct, where reality is reduced to, and interpreted as, *text*, tool augmentation other than that related to natural language (e.g., metaphor) would be superfluous and CT/TC would lose its *raison d'être*. The belief that the human mind *is* molded by tools and open to scientific scrutiny also dissociates CT/TC from any theoretical framework that is essentially behaviorist in nature (*see* **Behaviorism: Varieties**).

Methodology for Tool Design

Dialectic adaptation of the mind to the operations of its tools – a process that is often tool-coerced – leads to technological change. Increased technological sophistication forces us to make ethical choices. Of interest here is a search for design methods and practice capable of eliminating, before they even arise, any undesirable effects of tool use on users. The main question is "Which design methods and practice will result in tool-mind-world hybrids that optimally benefit humankind?" CT, understood as a methodology for design, is thus a process: an approach to design, not a product of such a design. We can design

Scholarly Discipline

The primary area of inquiry is Technological Cognition (TC), which examines what happens to humans when they augment themselves with technologies, either physically or cognitively, to amplify their natural capabilities. The aim of CT/TC is to formulate and to test theories of human cognitive processes that interact with technological artifacts and are partially formed by those interactions. As a fluid, symbiotic hybrid of the embodied mind and its tools, such a technologized cognition has epistemic effects: It affords an understanding and control of the external world that otherwise would not have been possible. As rational agents, humans develop and use tools to empower themselves in the *real* world which exists independently of them. This places CT/TC firmly in the realist tradition, in direct contrast with the assumptions of postmodernism (*see* **Postmodernism**): if the external world were merely a social construct, where reality is reduced to, and interpreted as, *text*, tool augmentation other than that related to natural language (e.g., metaphor) would be superfluous and CT/TC would lose its *raison d'être*. The belief that the human mind *is* molded by tools and open to scientific scrutiny also dissociates CT/TC from any theoretical framework that is essentially behaviorist in nature (*see* **Behaviorism: Varieties**).

Methodology for Tool Design

Dialectic adaptation of the mind to the operations of its tools – a process that is often tool-coerced – leads to technological change. Increased technological sophistication forces us to make ethical choices. Of interest here is a search for design methods and practice capable of eliminating, before they even arise, any undesirable effects of tool use on users. The main question is "Which design methods and practice will result in tool-mind-world hybrids that optimally benefit humankind?" CT, understood as a methodology for design, is thus a process: an approach to design, not a product of such a design. We can design

Figure 1 Anthropocentric CT design versus traditional human-centered design.

tools in accordance with CT principles, informed by the theoretical developments of TC, but those tools are not in themselves instances of CT.

The search for ethical factors in tool design means that studies undertaken within CT are primarily about people and not about the technologies that augment them. This distinguishes CT from investigations of the so-called human factors in designing human-centered systems that promote 'naturalness' in human-tool exchanges and aim at designing ergonomic, user-friendly tools, in order to fully accommodate the limits of human performance and fully exploit the advantages of the user (as it is practiced in areas such as Cognitive Ergonomics, Cognitive Engineering, and Engineering Psychology). What such practices do not overtly address is the question of who really stands to benefit. Nor do they explicitly consider that every tool is a prosthetic device (some mental functions become redundant), that the user/tool relation is of one-to-many (with the dangers of stress overload), that sophisticated tools can obscure dignity at work, that they separate people from their natural habitat or change their perception of their own competence. By contrast, CT aims to bring humane factors to bear on design. The tool-mind-world hybrids designed according to the principles of CT are intended to be essentially anthropocentric, i.e., they maximize human (user) benefits (see Figure 1).

Mind-Amplifying Tool

CT takes a broad view of technology. All artifacts are in some measure cognitive tools. We need to understand them in terms of their goals and computational constraints as well as in terms of the external physical and social environments that shape and afford cognition. Any technology that serves that purpose by providing a tool has implications for CT/TC.

Cognitive tools can be situated on a continuum of purposeful use between the extremes of raw material and the brain. They can be more or less externalized or detached from the brain or the body (cf. bionic prostheses incorporating direct brain implants with word processors vs. spades). The greater the detachment, the lower the brain-tool connectivity and alignment. The lower the connectivity, the lower the ability to attend to the feedback the brain receives at the interface; consequently, the less the need for people to adapt to the tool. Within this continuum, we can distinguish between natural technologies and fabricated technologies.

Natural Technologies

Natural technologies are instances of mental *techné*, i.e., learned skills and mental competencies. Examples proposed within CT include a body image generator responsible for perceiving one's own body size, the cognitive processes within the prefrontal cortex responsible for our social competence, or the cognitive processes evolved in autism. Here also belong learned aspects of natural language (*see* **Whorf, Benjamin Lee (1897–1941)**), narratives, mnemonic systems for improving memory, task-dedicated cognitive processes in logic and arithmetic, or metaphors in cultural heritage. The mind itself can be viewed as a complex, goal-driven toolkit of natural cognitive artifacts that bootstrap on what is hard-wired, in order to make available a much bigger set of such artifacts. The mind thus facilitates interactions with the environment through the organization and integration of perceptual data, memory, and goal-management.

Fabricated Technologies

While some fabricated technologies are tangible (pens, paper, computers, mechanical gadgets, telecommunication devices, medical equipment, or flight simulators are obvious examples), others are not, but nonetheless they affect our mental capabilities and competences: e.g., writing systems, narratives, artificial languages, and so on.

Cybernetic systems such as robots can become a scientist's cognitive tools if they are built to further scientific progress. They have been applied to understand how categorical perception works, how intelligence of natural systems is embodied, and to the question of whether there is a fundamental distinction between humans and machines. In artificial intelligence, computation has been employed to formulate and to test theories of intelligence or the nature of consciousness. In computational linguistics (*see* **Computational Linguistics: History**), automated grammars have aided linguists in their efforts to understand the workings of natural language.

Any systematized environment that constrains cognition results in cognitive change. Perhaps the best example is a prison system where people become habituated to its inherent operations; many are unable to function effectively upon release. Or, take an organizational merger: Its most challenging aspect is consolidating the diversity of employees' mental cultures.

Perspectives on Mind Change

The simplest form of cognitive change is learning, and many technologies are purposefully developed to this end. While people will adapt to any technology, the extent of their adaptation depends on the extent of the cognitive fit between the human mind and the augmenting technology. When some mental processes are taken over by technology, the relevant natural technologies augment, too. A subsequent absence of the tool may then render the acquired *techné* ineffective. (As an example, consider the impact of word processors on generating texts.) Such a technological augmentation is not permanent and can be unlearned.

Technological augmentation can also have lasting effects. Longitudinal studies in archaeology reveal that cognitive fluidity can be directly linked to tool use. Studies in primatology and developmental psychology show that language constructs, in particular storytelling, played a crucial role in handling the complexity of the social dynamics responsible for the evolution of the primate brain. Social and narrative intelligence requires a larger neocortex, hence a bigger brain size.

Can we predict *a priori* the long-term effects of a given technology on the human user? The difficulty of this question has been recognized with respect to language. The meaning of a linguistic symbol depends on how, and in which context, it is used (*see* **Context, Communicative; Wittgenstein, Ludwig Josef Johann (1889–1951)**). Language becomes alive and unfolds its history via its interaction with people. Meanings transform across different epochs and different cultures as a result of interpreting and reinterpreting language. The context of its use, and the medium through which it is used, have a bearing on language itself. Consider the impact of the Internet and mobile phones (texting) on the art of conversation or the spelling of words. The same is true of any artifact. Internal structure of design and a form perceived at the interface are insufficient to derive the social and personal significance or the subsequent development of a piece of technology. The latter can only happen in the context in which it is used. In the absence of such context, there is no unique answer to the question "What is this artifact for?" Its affordances for action (the toolness of a tool) only become manifest when the mind comes in contact with it in some context.

To predict the consequences of tool use, it is necessary (though not sufficient) to understand the social, psychological, and cognitive mechanisms that create the need for technological augmentation. A theoretical framework with a potential for such investigations must necessarily deal with motives and benefits, in other words, with *relevance*. Within CT, the Theory of Relevance, originally developed with respect to language use (*see* **Relevance Theory**), has been broadened to encompass all cognitive processes (symbolic and connectionist) involved in action planning and goal management. This extended framework can be invoked to explain the modularity of mind and remove a variety of difficulties experienced in the symbol-driven acquisition of natural technologies or the design of fabricated ones. It provides grounds for classifying a dedicated inferential comprehension module as an instance of natural CT. By recognizing a multitude of cognitive interfaces (e.g., between perception, consciousness, knowledge, motivation, emotion, action, natural/fabricated technologies, external situations), the extended framework can assist the exploration of (1) the extent to which the constraints on our mental life are biologically or technologically determined, and (2) how language *techné* interacts with other aspects of cognition, facilitating, ultimately, the choice between various proposals for developing a humanized linguistic technology. Even so, the big question, whether, and to what extent, technology can be humanized, remains an open question (*see* **Adaptability in Human-Computer Interaction**).

Coherence: Psycholinguistic Approach

Coherence in Text and in the Mind

A text is coherent to the extent that it is intelligible, that there are no aspects of the text that do not relate to the message, and that there is no sense that things are missing from the text. We may judge a text as incoherent if these conditions are not met. There are two important sources of information that contribute to coherence: text cues and psychological constraints. Text cues are simply those cues that are in the text itself, while psychological constraints refers to processes of thought or inference that add to what is given by the text. Of course, if as a result of the way it is written we have to make too many poorly-guided inferences to understand a message, then we may say that the text itself appears incoherent. From a psychological perspective, a coherent text may be thought of as one that brings to mind just the right things to facilitate easy understanding, while an incoherent text is one that fails to do that, leaving the reader or listener with no sense of understanding the message. Texts that present the reader or listener with a difficult task may be judged more or less coherent.

This raises an interesting question: how to define a text as distinct from a random concatenation of sentences. There has been a tradition in text linguistics that claims that coherence is an intrinsic defining property of a text. Pieces of writing that do not conform to the principles underlying coherence are taken either to be defective (suboptimal) or not texts at all. For instance, a text that is coherent must have clauses that are clearly connected to one another. Second, the clauses must logically relate to one another, and third, each sentence must somehow be relevant to the overall topic of the discourse. Some of these requirements can be met from what is actually written in the text itself. For instance, texts can contain explicit cohesion markers that provide links between the clauses of a text. But the other requirements, such as clauses logically relating to one another, and the clauses being relevant to the overall topic of the discourse are plainly psychological; they require the reader/listener to perceive relevance. We shall amply illustrate this point in this article.

The psychological view is that coherence is something that depends on the mental activity of the reader or listener, on their capacity to understand the message that the producer of the text is trying to convey. The text can be thought of as providing clues as to what the message is, but the reader has to use these cues. So, from a psychological perspective, we may ask what mental processes lead to the development of a coherent mental representation of the text (knowledge of the message), and what clues in texts help to guide these processes appropriately (see Gernsbacher and Givon, 1995, for a broad perspective).

Coherence: Psycholinguistic Approach

A Sanford, University of Glasgow, Glasgow, Scotland, UK

© 2006 Elsevier Ltd. All rights reserved.

Coherence in Text and in the Mind

A text is coherent to the extent that it is intelligible, that there are no aspects of the text that do not relate to the message, and that there is no sense that things are missing from the text. We may judge a text as incoherent if these conditions are not met. There are two important sources of information that contribute to coherence: text cues and psychological constraints. Text cues are simply those cues that are in the text itself, while psychological constraints refers to processes of thought or inference that add to what is given by the text. Of course, if as a result of the way it is written we have to make too many poorly-guided inferences to understand a message, then we may say that the text itself appears incoherent. From a psychological perspective, a coherent text may be thought of as one that brings to mind just the right things to facilitate easy understanding, while an incoherent text is one that fails to do that, leaving the reader or listener with no sense of understanding the message. Texts that present the reader or listener with a difficult task may be judged more or less coherent.

This raises an interesting question: how to define a text as distinct from a random concatenation of sentences. There has been a tradition in text linguistics that claims that coherence is an intrinsic defining property of a text. Pieces of writing that do not conform to the principles underlying coherence are taken either to be defective (suboptimal) or not texts at all. For instance, a text that is coherent must have clauses that are clearly connected to one another. Second, the clauses must logically relate to one another, and third, each sentence must somehow be relevant to the overall topic of the discourse. Some of these requirements can be met from what is actually written in the text itself. For instance, texts can contain explicit cohesion markers that provide links between the clauses of a text. But the other requirements, such as clauses logically relating to one another, and the clauses being relevant to the overall topic of the discourse are plainly psychological; they require the reader/listener to perceive relevance. We shall amply illustrate this point in this article.

The psychological view is that coherence is something that depends on the mental activity of the reader or listener, on their capacity to understand the message that the producer of the text is trying to convey. The text can be thought of as providing clues as to what the message is, but the reader has to use these cues. So, from a psychological perspective, we may ask what mental processes lead to the development of a coherent mental representation of the text (knowledge of the message), and what clues in texts help to guide these processes appropriately (see Gernsbacher and Givon, 1995, for a broad perspective).

Cohesion Markers

One thing that can be seen in texts is a so-called cohesion marker (see Halliday and Hasan, 1976). This marker may be a connective, like *and*, *but, when, while, because, so, therefore, hence*, and so on. Another form of connection is anaphora – using a term that relates a concept back to one that was previously introduced, as in (1):

(1) John came home **because he** was missing his mother.

Here, *because* is a connective that links the two clauses, and *he* is an anaphoric pronoun that refers back to John. Both of these devices provide some glue to connect the two clauses, and help bind them into a coherent whole. The devices are visible in the text itself. There are many other cues that signal relationships between the parts of text, expressions like *first* (which cues that there will be a successor), *next, later, finally*, *after that* (signaling temporal progressions), *similarly,* and *in the same way* (signaling various ways in which clauses or phrases may be related to one another). Such cues are only cues, of course, and they are neither sufficient nor necessary for a text to appear coherent. So, a text with ample coherence markers may be quite incoherent:

(2) John ate a banana. The banana that was on the plate was brown, and brown is a good color for hair. The hair of the dog is a drink to counteract a hangover.

Such texts are not truly coherent, in the sense that they do not produce an obvious message. So the presence of cohesion markers is not enough to guarantee coherence. The clauses in a text need to be sensibly related and to form a sensible whole. Of course, what is sensible depends upon comparing what is being said in the text with what the reader knows about the world. It is clearly a matter of psychology, not just of what is in the text.

Cohesion markers are not necessary for finding a text to be coherent, either. For instance, consider the following:

(3) Mr. Smith was killed the other night. The steering on the car was faulty.

Although there is no stated connection between the two sentences, readers infer that the second sentence provides the reason for the state of affairs depicted in the first sentence, and that makes the text coherent. There is no cue to this in the text itself. In (4) there is such a cue:

(4) Mr. Smith was killed the other night, **because** the steering on the car was faulty.

So, although explicit connectives may indicate the relationship between different clauses and propositions, a text may be quite coherent even in the absence of such markers, as shown in (3).

What psychological studies have shown is that for some connectives, their presence does indeed aid comprehensibility. For instance, if people read short stories where the last sentence either did or did not begin with a connective (for instance, *However, the pilot made a safe landing*), they spend less time reading the final sentence when an explicit connective is used than when it is not. The mental representation of sentences that have clauses linked by causal connectives seem to be more stable as well, since they are better remembered than those that are not directly linked. So although it may be possible to infer the link between two clauses, an explicit cue does help, and of course, may sometimes be necessary.

The Psychological Concept of a Connected, Coherent, Discourse Representation

An almost universal view, within psychology, of how text is processed is that the text expresses ideas that become connected to form a coherent whole. A parallel idea in text linguistics is that each part of a text is linked to at least one other part by some sort of relation (called rhetorical predicates, *see* **Rhetorical Structure Theory**). The idea is similar: that coherence results from being able to appropriately relate each bit of the discourse to some other, so that a connected whole results; however, the psychological approach is concerned with studying how the connections are established, and what are the mental entities that come to be related to each other. The end point is the mental representation of the discourse and is part of memory. Because memory is fallible, the final representation will be incomplete too.

As discussed above, connectives (explicit or inferred) are partly responsible for the local coherence of pieces of text (adjacent pairs of sentences, say). But a text will give rise to a coherent mental representation at several levels. It is possible to illustrate some aspects of connectivity with the following example:

(5) (a) Harry was trying to clean up the house. (b) He asked Mary to put the book in the box on the table. (c) She said she was too busy to do that. (d) She had to write out a check for her friend Jill because she had no money left. (e) Harry nearly exploded. (f) He thought that they spent too much money on charities as it was. (g) Mary suddenly burst into tears.

Connecting Individuals: Anaphoric Reference

The same individuals appear over and again in this simple story. *Harry* in (a) is *He* in (b), *Harry* in (e), and *He* in (f). Identifying Harry in this way is important, since that way we can connect the actions and reactions of that individual. Sometimes *Harry* is used in preference to *He*, as in (e). Using a name like this occurs especially when the individual concerned has not been at the center of the unfolding text (in focus) for a while; psycholinguistic work has shown that the use of a name is especially useful when a character is being 'reintroduced,' as Harry is in (e). Use of *He* would still be intelligible, but slower processing of the sentence would result, showing a difficulty with using a pronoun.

Processing difficulties are minimized with the character Harry because there is only one male character in the story. But the situation with Mary is different because there are two female characters, with Jill introduced in (d). In fact, in sentence (d), the reader has to work out who *she* is from general knowledge, not from the text. In this case, because it would be a person with money who could give money to someone without money, the second *she* is treated as coreferential with Jill, not Mary. Psychological work has shown that such inferential processes, although they seem automatic, are time-consuming.

A further anaphoric connector in the passage is worthy of note. First, in (c), there is *that*. Here the expression refers to the event *Mary puts the book in the box on the table*. Terms like *this* and *that* can refer to huge conglomerations of events, as in a very complex story leading to the statement *This was too much for Harry*. So, to summarize, anaphoric devices are vital to producing a coherent mental representation of who did what. A major review of psychological work on anaphora was Garnham (2000).

Causal Connectivity

With narrative texts especially, the reader has to establish causal links between the various parts of the text, and the whole structure gives rise to global coherence. So, in (a), Harry is given a goal. In (b), a further action is introduced. How is this interpreted? Most people interpret the action as being part of realizing this goal. However, there is nothing in the text to indicate this. In our example, there is hardly anything to tell the reader what the causal structure is. In the passage below, we have included some connectives that fill out the causal structure:

(6) Harry was trying to clear up the house. **TO HELP WITH HIS GOAL** He asked Mary to put the book in the box on the bookshelf. **HOWEVER** (BLOCKING HIS GOAL) She said that she was too busy to do that. **THE REASON WAS** She had to write out a check for her friend Jill because she had no money left. **AS A RESULT OF THIS REASON** Harry nearly exploded. **THE REASON WAS** He thought they spent too much on charities as it was. **AS A RESULT** Mary suddenly burst into tears.

In order to achieve a very minimal understanding of this text, the information provided in bold, or something like it, must be inferred by the reader and incorporated into their mental representation of the discourse. A number of studies have shown that judgments of how clearly the clauses of texts are causally related predicts a number of performance measures during reading, including the time taken to read sentences, judgments of how well sentences fit into texts, the judged coherence of texts as a whole, and the ease of recalling texts (see Langston and Trabasso, 1999). When people understand texts, they appear to do so by forming mental representations consisting of causal chains, and the robustness of the causal chains reflects coherence.

Studies of Inferential Activity

Necessity and Elaboration

Everywhere in discourse, readers are called upon to make inferences; without them, there would be no coherence. A key distinction is made between inferences that are necessary for coherence and inferences that are not necessary, but rather just fill out the picture being portrayed by the writer. Inferring causal relations, and anaphoric relations, are generally considered to be necessary inferences. In general, when a necessary inference is made, it can be shown to take time. One classic case (Haviland and Clark, 1974) is:

(7) Harry took the picnic things from the trunk.
(8) The beer was warm.

On reading (8), to understand how *The beer* fits into things, the reader must infer that beer was part of the picnic supplies. Sentence (8) took longer to read after (7) than it did after (9):

(9) Harry took the beer from the trunk.

Thus measurable time is needed to make the necessary bridging inference. Bridging inferences are assumed to be made only when necessary, when a gap in the connectivity of clauses is detected. There is no inference that beer might be part of the picnic things when just sentence (7) is read; rather, the inference is triggered when (8) is encountered. So such inferences are also called **backwards** inferences.

Necessary backwards-bridging inferences are contrasted with forward elaborative inferences. For instance, given (10), what might one infer?

(10) Unable to control his rage, the angry husband threw the valuable antique vase at the wall.

There are many possibilities, but a highly plausible one is that the vase broke. If on reading (10) this inference were made, then it would be an elaboration over what was said, and as it is not made because it is needed, it is called a forward inference. If this were followed by (11), the forward inference would facilitate comprehension:

(11) It cost well over $100 to replace.

But such an inference would not help us understand (12):

(12) He had been keeping his emotions bottled for weeks.

There has been much debate over whether such elaborative inferences are typical, and if and when they are made. Clearly there are many such inferences that might be made. For instance, given (11), one might infer that the wife of the angry husband might be in some danger, that the husband might become more violent, that he felt ashamed afterwards, etc. Do we make all, or any, of such plausible inferences?

Because such inferences are indeed so plausible, it might be supposed that they are routinely made. In order to test whether an inference has been made, a variety of priming tasks have been used. With these, a test word is presented after a short passage. For instance, after (10), the test word BROKE might be presented. This word would also be presented after a sentence in which information pertinent to breaking is absent. Subjects are asked to read out loud the test word when it appears. The critical question is whether the word is read more rapidly after a priming sentence (11), when compared with a nonpriming sentence. If the word is read more rapidly, then it has been primed, and this suggests that the inference that the vase had broken had been made. Several different tests have been devised based on this idea. Under some circumstances, there has been weak evidence for such forward inferences happening immediately, though the general view is that they are made only under very constrained conditions and are not typical. The paucity of evidence for elaborative inferences was summed up in McKoon and Ratcliff (1992), who put forward the idea that during reading, immediate forwards elaborative inferences are typically minimal, and inferences are largely restricted to the necessary, backward, variety. However, in the long term, elaborative inferences have to be made, since comprehension is only possible when a mental model of what the text is about is constructed. We shall go on to look at some aspects of such a model.

Situation-Specific Information: Scenario-Theory

For a discourse to be understood, it has to be situated with respect to background knowledge. For instance:

(13) John drove to London yesterday.
(14) The car broke down halfway.

Superficially, this is similar to examples (7) and (8), in that a backwards-bridging inference could be made to link *The car* in (14) to *drove* in (13). Such a backwards-inference would be time-consuming for reading (14). However, several studies have shown that the time to read (14) is no greater to read after (13) than it is after (15), where the car is mentioned explicitly:

(15) John took his car to London yesterday.

The key difference between *The car* in (15) and *The beer* in (8) is that *car* is typically definitional of driving, whereas *beer* is just a plausible option for picnic things. So, for entities that are part of the meaning of actions, those entities appear to be included in the representation of the sentence depicting the action. The concept <car> is part of the representation of the action *drove to a place*. Sanford and Garrod (1981, 1998) put forward the idea that when we read a text, we identify as quickly as possible the background situation in which the propositions in the text are grounded; they further assumed that much of what we know is represented in a situation-specific way, in structures that they termed scenarios. Driving is one example, where the concept <car>, and expected actions, are represented. Another well-known illustration is of having a meal in restaurant, where the events, the order of events (find table, get waiter, order meal, eat courses in expected order, get bill, pay, leave, etc.), and the principle actors (customer, waiter, wine-waiter) are represented. In general, if a new entity is introduced into a text, either it will already be part of the prior representation (scenario), or a backwards inference will have to made.

Using situation-based knowledge is essential for developing a coherent representation, and a simple example is:

(16) Fred put the wallpaper on the table. Then he rested his mug of coffee on the paper.

This pair of sentences is immediately coherent; nothing seems out of place. However, (17) depicts an unrealistic state of affairs, and this is immediately recognized:

(17) Fred put the wallpaper on the wall. Then he rested his mug of coffee on the paper.

Sentences (16) and (17) depict different situations: putting wallpaper on a table leaves the paper as a horizontal surface, while putting it on the wall leaves it in a vertical plane, so that the cup would just fall down. The implication is that people try to build a representation of what is being depicted with the each pair of sentences, and in order to do that, they have to use situation-specific knowledge.

Keeping Track of Things: Situation Models The kind of situation-specific knowledge discussed above is stereotyped, and connecting language input to representations of specific situations is essential for adequate understanding, and hence coherence. But this is plainly not enough, in that texts do not simply refer to static situations; rather, as they unfold they depict a dynamic passage of events. Even the simple example (6) serves to illustrate that, which is why the development of a causal chain is so important for a coherent representation.

A bold attempt to grasp the nettle of this more dynamic aspect of comprehension is found in the concept of the situation model (see Zwaan and Radvansky, 1998 for a detailed overview). They propose that as texts unfold, readers may keep track of a number of things. Consider first space. In some stories, people move around in space, and there is evidence that readers keep track of these movements. So, it turns out that readers have faster access to mental representations of rooms where protagonists are, or toward which protagonists are heading, than to representations of other rooms. This suggests two things: readers take the perspective of protagonists (see Duchan *et al.*, 1995, for an introduction to this issue), and they update the focus of interest to where the protagonist is, or is said to be heading. Of course, not all stories are about events in space, but when they are, readers generally update where the protagonist is in their mental representation of the text.

Several researchers have suggested that there are at least five dimensions to situations that could be encoded by the reader: space (as above), time, causation (briefly discussed above), intentionality, and protagonist. It has been plausibly argued that the comprehension of narratives revolves around keeping track of the goals and plans of protagonists (intentionality). It has been shown by probing readers that they appear to make inferences based on what motivates the actions of protagonists, even when this information is not directly available. The protagonist category refers to the people and things in the mental representation. They are the entities that are being updated with respect to place, time, and intentionality. This category leads to a further aspect that has to be understood about characters if coherence is to be achieved: the emotions of the protagonists. Experimental evidence suggests that the emotional states of protagonists might be inferred as forward inferences (see the classic work of Gernsbacher *et al.*, 1992).

Multiple Viewpoints A further aspect of coherence is that with many texts, alternative versions of reality may have to be entertained if the text is to be understood. Consider (18):

(18) John put his wallet on the dresser. Unbeknownst to John, Mary later moved it to his bedside table. When he came in from gardening, John went to get his wallet. First he tried his bedside table.

John's action doesn't make sense in our situation model, because we represent what John believes is the location of his wallet, and we also represent where the wallet actually is. The capacity to capture the beliefs of others and how these beliefs relate to what we know to be reality is called having a 'Theory of Mind.' Without the capacity to make these representations, texts like (18) could not be understood as anomalous, and would display apparent coherence that was unwarranted. Dealing with multiple viewpoints like this has received some attention, and given its prevalence in narratives and real-life situations, deserves more. However, one major discovery is that some people do not have the capacity to handle these multiple perspectives (it is particularly a feature of autism; see Baron-Cohen, 1995; for a very detailed analysis of multiple viewpoints and coherence, see Fauconnier, 1994).

Coherence and Selective Processing

We have portrayed coherence as the establishment of connections between things mentioned in a text, actions mentioned in a text, and world knowledge supporting interpretation. There is an extra ingredient that has to be included, and that is selectivity in processing. Not all parts of texts are equally important, and a key aspect of coherence is being able to sort out what is important from what is mere detail (or even irrelevant). Coherence derives from not merely being able to join up what is in a text and relate it to knowledge, but to be able to selectively attend to what is salient – the gist of a message.

Selective Processing

Ideas as to what constitutes the gist of a text have been around since the seminal work of Walter Kintsch and his colleagues (see Kintsch, 1977, for a sample of this important work). Essentially, the idea was that what was in texts could be expressed as propositions (or idea units). Furthermore, some propositions were dependents of others, and that the less dependent a proposition, the closer it corresponded to gist. Consider the following:

(19) Harry was tired. He planned to go on package holiday to Greece.

In the second sentence, we learn that Harry planned to go on holiday (the key proposition), that the type of holiday was a package holiday (a dependent proposition: there can be no package holiday without there being a holiday), and that the holiday was in Greece (another dependent proposition). Many experiments on summarizing texts, and on remembering texts, showed that summaries and memories tended to lose dependent propositions. Thus a 'gist' representation of (19) might include *Harry planned a holiday*, but might exclude the package-deal component, or the fact that he planned to take it in Greece (unless these details become more salient later).

There are cues in the structure of texts themselves as to what might be the most important information. For instance, discourse focus is a device for indicating where salient information lies. In (20), the salient information is *with the hat*, because that specifies which man was arrested. In (21), however, *with the hat* is merely an incidental attribute of the man.

(20) Q: Which man was it who was in trouble?
A: The man with the hat was arrested.
(21) Q: What was it that happened last night?
A: The man with the hat was arrested.

Recent experiments have shown that if subjects read a text similar to (20) once, and then immediately afterwards read the same thing again, but with hat changed to cap, they tend to notice the change. But if they read (21), they tend not to notice the change. Focus influences what is important, and how deeply the text is processed, showing how it controls patterns of understanding (see Sanford and Sturt, 2002, for a review of shallow processing).

Other aspects of text structure influence what is taken into account in producing a coherent representation. Emphasis may be put on quite different aspects of a state of affairs by simple devices in language, such as negation and quantification. For instance, here are two ways of depicting the fat content of a product:

(22) This product is 90% fat free.
(23) This product contains 10% fat.

Experiments have shown that people judge products to be less greasy and more healthy if the second of these descriptions is used (even if they taste a product). This is because the first description focuses on the amount of nonfat, whereas the second focuses on the amount of fat. Such focusing can happen implicitly, if terms are negative. Experimental work has shown that both of these statements are coherent, but in the fat-free case, people do not interpret the amount of fat-freeness against how much fat would be good or bad in a product. The fat-free formulation inhibits the use of world-knowledge, while the %-fat formulation does not inhibit it. Thus 75% fat free and 95% fat free are both considered to be more or less equally a good thing, while 25% fat is considered to be much less healthy than 5% fat (see Sanford and Moxey, 2003, for a review of these arguments for a variety of situations).

Linking together different elements in a text and linking text to knowledge are important for a coherent interpretation of a text to be made; so too is being selective by choosing perspectives to build coherent structures around, and being selective to avoid over-elaborating inferences that are not relevant. To achieve these goals, the writer or speaker has to choose the right linguistic devices and forms of words to guide the reader/listener into making the right inferences, using the sort of knowledge the producer intended. The capacity of a producer to do this effectively is what makes the discourse they are producing appear coherent.

Cohesion and Coherence: Linguistic Approaches

T Sanders and H Pander Maat, Utrecht Institute of Linguistics OTS, Utrecht University, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Discourse is more than a random set of utterances: it shows connectedness. A central objective of linguists working on the discourse level is to characterize this connectedness. Linguists have traditionally approached this problem by looking at overt linguistic elements and structures. In their famous *Cohesion in English*, Halliday and Hasan (1976) describe text connectedness in terms of reference, substitution, ellipsis, conjunction, and lexical cohesion. According to Halliday and Hasan (1976: 13), these explicit clues make a text a text. Cohesion occurs "when the interpretation of some element in the discourse is dependent on that of another" (Halliday and Hasan, 1976: 4). The following types of cohesion are distinguished.

- *Reference*: two linguistic elements are related in what they refer to.

  Jan lives near *the park*. *He* often goes *there*.

- *Substitution*: a linguistic element is not repeated but is replaced by a substitution item.

  Daan loves strawberry *ice-creams*. He has *one* every day.

- *Ellipsis*: one of the identical linguistic elements is omitted.

  All the children had an *ice-cream* today. Eva chose strawberry. Arthur had orange and Willem too.

- *Conjunction:* a semantic relation is explicitly marked.

  Eva walked into town, *because* she wanted an ice-cream.

- *Lexical cohesion:* two elements share a lexical field (*collocation*).

  Why does this little *boy wriggle* all the time? *Girls* don't *wriggle* (Halliday and Hasan, 1976: 285).

  It was *hot*. Daan was lining up for an *ice-cream*.

While lexical cohesion is obviously achieved by the selection of vocabulary, the other types of cohesion are considered as grammatical cohesion. The notion of lexical cohesion might need some further explanation. Collocation is the most problematic part of lexical cohesion (Halliday and Hasan, 1976: 284). The analysis of the first example of lexical cohesion above would be that *girls* and *boys* have a relationship of complementarity and are therefore related by lexical cohesion. The basis of lexical cohesion is in fact extended to any pair of lexical items that stand next to each other in some recognizable lexicosemantic relation. Let us now consider the second example of lexical cohesion mentioned above. Do *hot weather* and *ice-cream* belong to the same lexical field? Do they share a lexicosemantic relationship? If we want to account for the connectedness in this example, we would have to assume that such a shared lexicosemantic relationship holds, since the other forms of cohesion do not hold. The clearest cases of lexical cohesion are those in which a lexical item is replaced by another item that is systematically related to the first one. The class of general noun, for instance, is a small set of nouns having generalized reference within the major noun classes, such as 'human noun':

Cohesion and Coherence: Linguistic Approaches

T Sanders and H Pander Maat, Utrecht Institute of Linguistics OTS, Utrecht University, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Discourse is more than a random set of utterances: it shows connectedness. A central objective of linguists working on the discourse level is to characterize this connectedness. Linguists have traditionally approached this problem by looking at overt linguistic elements and structures. In their famous *Cohesion in English*, Halliday and Hasan (1976) describe text connectedness in terms of reference, substitution, ellipsis, conjunction, and lexical cohesion. According to Halliday and Hasan (1976: 13), these explicit clues make a text a text. Cohesion occurs "when the interpretation of some element in the discourse is dependent on that of another" (Halliday and Hasan, 1976: 4). The following types of cohesion are distinguished.

- *Reference*: two linguistic elements are related in what they refer to.

  Jan lives near *the park*. *He* often goes *there*.

- *Substitution*: a linguistic element is not repeated but is replaced by a substitution item.

  Daan loves strawberry *ice-creams*. He has *one* every day.

- *Ellipsis*: one of the identical linguistic elements is omitted.

  All the children had an *ice-cream* today. Eva chose strawberry. Arthur had orange and Willem too.

- *Conjunction:* a semantic relation is explicitly marked.

  Eva walked into town, *because* she wanted an ice-cream.

- *Lexical cohesion:* two elements share a lexical field (*collocation*).

  Why does this little *boy wriggle* all the time? *Girls* don't *wriggle* (Halliday and Hasan, 1976: 285).

  It was *hot*. Daan was lining up for an *ice-cream*.

While lexical cohesion is obviously achieved by the selection of vocabulary, the other types of cohesion are considered as grammatical cohesion. The notion of lexical cohesion might need some further explanation. Collocation is the most problematic part of lexical cohesion (Halliday and Hasan, 1976: 284). The analysis of the first example of lexical cohesion above would be that *girls* and *boys* have a relationship of complementarity and are therefore related by lexical cohesion. The basis of lexical cohesion is in fact extended to any pair of lexical items that stand next to each other in some recognizable lexicosemantic relation. Let us now consider the second example of lexical cohesion mentioned above. Do *hot weather* and *ice-cream* belong to the same lexical field? Do they share a lexicosemantic relationship? If we want to account for the connectedness in this example, we would have to assume that such a shared lexicosemantic relationship holds, since the other forms of cohesion do not hold. The clearest cases of lexical cohesion are those in which a lexical item is replaced by another item that is systematically related to the first one. The class of general noun, for instance, is a small set of nouns having generalized reference within the major noun classes, such as 'human noun':

people, *person*, *man*, *woman*, *child*, *boy*, *girl*. Cohesion achieved by anaphoric reference items like *the man* or *the girl* is very similar to cohesion achieved by reference with pronouns like *he* or *she*, although Halliday and Hasan (1976: 276) state explicitly what the difference is: "the form with general noun, *the man*, opens up another possibility, that of introducing an interpersonal element into the meaning, which is absent in the case of the personal pronoun." This interesting observation points forward to similar observations formulated in theories developed much later, as in *Accessibility Theory* (Ariel, 1990) and *Mental Space Theory* (Fauconnier, 1994; Fauconnier and Sweetser, 1996; Sanders and Redeker, 1996). This is only one example in which *Cohesion in English* shows itself to be a seminal work, in some respects ahead of its time.

After the publication of *cohesion in English*, the notion of cohesion was widely accepted as a tool for the analysis of text beyond the sentence level. It was used to characterize text structure, but also to study language development and written composition (Lintermann-Rygh, 1985). Martin's *English text* (1992) is a more recent elaboration of the cohesion work. It also starts from a systemic functional approach to language and claims to provide a comprehensive set of discourse analyses for any English text.

Useful and seminal as the cohesion approach may be, there seem to be some principled problems with it. For instance, the notion of lexical cohesion is hard to define. The intuition that 'hot weather' and 'ice-cream' belong to the same lexical field may be shared by many people in modern Western culture, but now consider example (1).

(1) The winter of 1963 was very cold. Many barn owls died.

Here it is much harder to imagine that 'cold winters' and 'barn owls,' or even 'dying barn owls,' should be related by a lexical field. Still, relating these items is necessary to account for the connectedness in (1). This problem is hardly solved by Halliday and Hasan's (1976: 290) advice "to use common sense, combined with the knowledge that we have, as speakers of a language, of the nature and structure of its vocabulary." Examples like (1) constitute a major problem for a cohesion approach: this short text presents no interpretation difficulties whatsoever, but there is no overt linguistic signal either. This suggests that cohesion is not a necessary condition for connectedness. Such a conclusion is corroborated by cases like (2), from a Dutch electronic newspaper (Sanders and Spooren, in press), to which we added the segment-indices (a) and (b).

(2a) Greenpeace heeft in het Zuid-Duitse Beieren een nucleair transport verstoord.
(2b) Demonstranten ketenden zich vast aan de rails. (*Telegraaf-i*, April 10, 2001)

(2a) 'Greenpeace has impeded a nuclear transportation in the Southern German state Bayern.'
(2b) 'Demonstrators chained themselves to the rails.'

This short electronic news item does not create any interpretative difficulties. However, in order to understand the fragment correctly, a massive amount of inferencing has to take place. For instance, we need to infer that the nuclear transportation was not disturbed by the *organization* Greenpeace, but by members of that organization; that the protesters are members of the organization; that the nuclear transportation took place by train, etc. Some of these inferences are based on world knowledge, for instance that organizations consist of people and that people, but not organizations, can carry out actions like the one described here. Others are based on discourse structural characteristics. One example is the phrase *the rails*. This definite noun phrase suggests that its referent is given in some way. But because there is no explicit candidate antecedent, the reader is invited to link it up with *transportation*, the most plausible interpretation being that the transportation takes place by a vehicle on rails, i.e., a train.

It is clear by now that the cohesion approach to connectedness is inadequate. Instead, the dominant view has come to be that the connectedness of discourse is a characteristic of the mental representation of the text rather than of the text itself. The connectedness thus conceived is often called *coherence* (*see* **Coherence: Psycholinguistic Approach**). Language users establish coherence by actively relating the different information units in the text.

Generally speaking, there are two respects in which texts can cohere:

1. *Referential coherence*: smaller linguistic units (often nominal groups) may relate to the same mental referent (*see* **Discourse Anaphora**);
2. *Relational coherence*: text segments (most often conceived of as clauses) are connected by coherence relations like Cause–Consequence between them (*see* **Clause Relations**).

Although there is a principled difference between the cohesion and the coherence approaches to discourse, the two are more related than one might think. We need to realize that coherence phenomena may be of a cognitive nature, but that their reconstruction is often based on linguistic signals in the text itself. Both coherence phenomena under consideration – referential

and relational coherence – have clear linguistic indicators that can be taken as processing instructions. For referential coherence these are devices such as pronouns and demonstratives, and for relational coherence these are connectives and (other) lexical markers of relations, such as cue phrases and signaling phrases. A major research issue is the relation between the linguistic surface code (what Givón, 1995, calls 'grammar as a processing instructor') and aspects of the discourse representation.

In the domain of referential coherence, this relation can be illustrated by the finding that different referential devices correspond to different degrees of activation for the referent in question. For instance, a discourse topic may be referred to quite elaborately in the first sentence but once the referent has been identified, pronominal forms suffice. This is not a coincidence. Many linguists have noted this regularity (e.g., Ariel, 1990; Givón, 1992; Chafe, 1994). Ariel (1990, 2001), for instance, has argued that this type of pattern in grammatical coding should be understood to guide processing. In her *accessibility theory*, 'high accessibility markers' use little linguistic material and signal the default choice of continued activation. By contrast, 'low accessibility markers' contain more linguistic material and signal the introduction of a new referent (*see* **Accessibility Theory**).

We now turn to (signals of) *relational coherence*. *Coherence relations* taken into account for the connectedness in readers' cognitive text representation (cf. Hobbs, 1979; Sanders *et al.*, 1992). They arealso termed *rhetorical relations* (Mann and Thompson, 1986, 1988, 1992) or *clause relations,* which constitute *discourse pattern*s at a higher text level (Hoey, 1983; *see* **Problem-Solution Patterns**). Coherence relations are meaning relations connecting two text segments. A defining characteristic for these relations is that the interpretation of the related segments needs to provide more information than is provided by the sum of the segments taken in isolation. Examples are relations like Cause-Consequence, List, and Problem-Solution. These relations are conceptual and they can, but need not, be made explicit by linguistic markers, so-called connectives (*because*, *so*, *however*, *although*) and lexical cue phrases (*for that reason*, *as a result*, *on the other hand*) (*see* **Connectives in Text**). In the last decade, a significant part of research on coherence relations has focused on the question of how the many different sets of relations should be organized (Hovy, 1990; Knott and Dale, 1994). Sanders *et al.* (1992) have started to define the 'relations among the relations,' relying on the intuition that some coherence relations are more alike than others. For instance, the relations in (3), (4), and (5) all express (a certain type of) causality; they express relations of Cause–Consequence/Volitional result (3), Argument–Claim/Conclusion (4) and Speech Act Causality (5): 'This is boring watching this stupid bird all the time. I propose we go home now!' The relations expressed in (6) and (7), however, do not express causal, but rather additive relations. Furthermore, a negative relation is expressed in (6). All other examples express positive relations, and (7) expresses an enumeration relation.

(3) The buzzard was looking for prey. The bird was soaring in the air for hours.

(4) The bird has been soaring in the air for hours now. It must be a buzzard.

(5) The buzzard has been soaring in the air for hours now. Let's finally go home!

(6) The buzzard was soaring in the air for hours. Yesterday we did not see it all day.

(7) The buzzard was soaring in the air for hours. There was a peregrine falcon in the area, too.

Sweetser (1990) introduced a distinction dominant in many existing classification proposals, namely that between content relations (also sometimes called ideational, external, or semantic relations), epistemic relations, and speech act relations. In the first type of relation, segments are related because of their propositional content, i.e., the locutionary meaning of the segments. They describe events that cohere in the world. If this distinction is applied to the set of examples above, the causal relation (3) is a content relation, whereas (4) is an epistemic relation, and (5) a speech act relation. This systematic difference between types of relation has been noted by many students of discourse coherence (*see* **Connectives in Text**). Still, there is a lively debate about whether this distinction should be conceived of in terms of domains, or rather in terms of subjectivity; often, semantic differences between connectives are used as linguistic evidence for proposals [see contributions to special issues and edited volumes like Spooren and Risselada (1997); Risselada and Spooren (1998); Sanders, Schilperoord and Spooren (2001); and Knott, Sanders and Oberlander (2001); further see Pander Maat (1999)]. Others have argued that coherence is a multilevel phenomenon, so that two segments may be simultaneously related on different levels (Moore and Pollack, 1992; Bateman and Rondhuis, 1997); see Sanders and Spooren (1999) for discussion.

So far, we have discussed connectedness as it occurs in both spoken/dialogical discourse and written/monological text. However, the connectedness of spoken discourse is established by many other means than the ones discussed so far. Aspects of discourse

structure that are specific to spoken language include the occurrence of *adjacency pairs*, i.e., minimal pairs like *Question-Answer* and *Summons-Response* (Sacks, Schegloff and Jefferson, 1974), and prosody. These topics are subject to ongoing investigations (see especially Ford, Fox and Thompson, 2001) that we consider important because they relate linguistic subdisciplines like grammar and the study of conversation.

In addition, it is clear that linguistic signals of coherence, such as connectives, have additional functions in conversations. For instance, connectives function to express *coherence relations* between segments, like *but* in example (8), which expresses a contrastive relation.

(8) The buzzard was soaring in the air for hours. But yesterday we did not see it all day.

In conversations, this use of connectives is also found, but at the same time, connectives frequently function as *sequential markers*: for instance, they signal the move from a digression back to the main line of the conversation or even signal turn-taking. In this type of use, connectives are often referred to as *discourse markers* (Schiffrin, 2001) (*see* **Particles in Spoken Discourse**).

In sum, we have discussed the principled difference between two answers to the question 'how to account for connectedness of text and discourse?' We have seen that, while cohesion seeks the answer in overt textual signals, a coherence approach considers connectedness to be of a cognitive nature. A coherence approach opens the way to a fruitful interaction between text linguistics, discourse psychology, and cognitive science, but at the same does not neglect the attention for linguistic detail characterizing the cohesion approach. The coherence paradigm is dominant in most recent work on the structure and the processing of discourse (see, among many others, Hobbs, 1990; Garnham and Oakhill, 1992; Sanders, Spooren and Noordman, 1992 ; Gernsbacher and Givón, 1995; Noordman and Vonk, 1997; Kintsch, 1998; Kehler, 2002). In our view it is this type of paradigm, located at the intersection of linguistics and discourse-processing research, that will lead to significant progress in the field of discourse studies.

Collitz, Hermann (1855–1935)

S Kürschner, Albert-Ludwigs-Universität Freiburg im Breisgau, Freiburg im Breisgau, Germany

© 2006 Elsevier Ltd. All rights reserved.

Hermann Collitz, one of the most influential comparative Indo-European linguists from Germany, spent much of his career in the United States. He was among the first linguistic scientists to move to the United States with the specific intention of working at American universities. Hermann Collitz was born on February 4, 1855 in Bleckede, Germany. He completed his linguistic studies at Halle, Berlin, and Göttingen, where he obtained a doctor's degree for his work on "the emergence of the Indo-Iranic row of palatals" (1879). His postdoctoral thesis ('habilitation') on nominal inflection in Old Indian and Greek was published in 1885 at the University of Halle, where he taught Sanskrit and comparative linguistics.

As a professor of German philology – and later as a professor of comparative philology – Collitz went abroad to teach at Bryn Mawr College in Philadelphia, Pennsylvania, in 1886. From 1907 to 1927, he was a professor at Johns Hopkins University, Baltimore, Maryland. In addition, Collitz stayed active in Germany and was among the editors of several books on Indo-European linguistics and dialectology. He worked on a dictionary of his own Low German dialect from Waldeck and concentrated on the dialectal history of Greek in several projects. In general philology, Collitz took part in the collection and editing of Greek dialectal inscriptions and did research on Indo-European mythology.

With his diachronic studies, Collitz was one of the pioneers in comparative linguistics. He specialized in the phonology and morphology of the Indo-European languages. Although he was supposed to be part of the group of Neogrammarians at Leipzig, which included Sievers, Paul, and Braune, these linguists could not persuade Collitz to take part in their activities. In contradiction to their radical theoretical approaches, Collitz stuck to the importance of sound changes in

Hermann Collitz, one of the most influential comparative Indo-European linguists from Germany, spent much of his career in the United States. He was among the first linguistic scientists to move to the United States with the specific intention of working at American universities. Hermann Collitz was born on February 4, 1855 in Bleckede, Germany. He completed his linguistic studies at Halle, Berlin, and Göttingen, where he obtained a doctor's degree for his work on "the emergence of the Indo-Iranic row of palatals" (1879). His postdoctoral thesis ('habilitation') on nominal inflection in Old Indian and Greek was published in 1885 at the University of Halle, where he taught Sanskrit and comparative linguistics.

As a professor of German philology – and later as a professor of comparative philology – Collitz went abroad to teach at Bryn Mawr College in Philadelphia, Pennsylvania, in 1886. From 1907 to 1927, he was a professor at Johns Hopkins University, Baltimore, Maryland. In addition, Collitz stayed active in Germany and was among the editors of several books on Indo-European linguistics and dialectology. He worked on a dictionary of his own Low German dialect from Waldeck and concentrated on the dialectal history of Greek in several projects. In general philology, Collitz took part in the collection and editing of Greek dialectal inscriptions and did research on Indo-European mythology.

With his diachronic studies, Collitz was one of the pioneers in comparative linguistics. He specialized in the phonology and morphology of the Indo-European languages. Although he was supposed to be part of the group of Neogrammarians at Leipzig, which included Sievers, Paul, and Braune, these linguists could not persuade Collitz to take part in their activities. In contradiction to their radical theoretical approaches, Collitz stuck to the importance of sound changes in

comparative linguistics. Independently of the German linguistic movements, Collitz became a strong advocate of the American philologies, which were widely ignored in Europe.

Hermann Collitz was honored in a *festschrift* (*Studies in honor of Hermann Collitz*, 1930) and – after his death – in several obituaries that cited his long list of works on Indo-European linguistics and especially the history of German, English, the other Germanic languages, and also Greek and Latin (cf. Sehrt, 1936). A list of four major monographs is supplemented by editorial work for several outstanding American journals such as *Modern Language Notes* and the *Journal of English and Germanic Philology*. Collitz founded the book series *Hesperia* with American work on Germanic philology and he published more than 70 articles and more than 30 book reviews. He received the honorary degree of L.H.D. from the University of Chicago in 1916. In 1925, he was the president of the Linguistic Society of America and the MLA. After retiring in 1927, Collitz remained an active philologist until his death on May 13, 1935.

Historical Use of the Term Collocation

The fact that certain words co-occurred frequently was noticed in Biblical concordances (e.g., Cruden listed the occurrences of *dry* with *ground* in 1769). Style and usage guides in the 19th and 20th centuries (e.g., Fowler's *The King's English*) addressed only the overuse of collocations, labeling them clichés and criticizing their use, especially by journalists (e.g., Myles na Gopaleen (see O'Nolan, 1977: 225–6), in a more humorous vein: 'When and again have I asked you not to do that? Time ... What is our civilization much? Vaunted. What is the public? Gullible. What interests? Vested.').

Collocation in Modern Linguistics

In modern linguistics, collocation refers to the fact that certain lexical items tend to co-occur more frequently in natural language use than syntax and semantics alone would dictate. Collocation was first given theoretical prominence by J. R. Firth, who separated it from cognitive and semantic ideas of word meaning, calling it an "abstraction at the syntagmatic level" (Firth 1957a: 196), and accorded it a distinct status in his account of the linguistic levels at which meaning can arise. Firth implicitly indicated that collocation required a quantitative basis, giving actual numbers of co-occurrences in some texts.

Halliday (1976) saw collocation as a cohesive device and identified the need for a measure of significant proximity between collocating items and said that collocation could only be discussed in terms of probability, thus validating the need for quantitative analyses and the use of statistics. Sinclair (Sinclair *et al.*, 1970) performed the first computational investigation of collocation, comparing written and spoken corpora, identifying ± five words as the span of significant proximity and experimenting with statistical measures and lemmatization.

Halliday (1966) and Sinclair (1966) thought that collocation could enable a lexical analysis of language independent of grammar. Sinclair (1991) suggested that lexical items could be defined by their collocational environments, saw collocation as part of the idiom principle (lexically determined choices), as opposed to the open choice principle (grammatically determined choices). Leech (1974: 20) included 'collocative' in his categories of meaning, but marginalized it as an idiosyncratic property of individual words, incapable of contributing to generalizations. Sinclair (1987c) and Stubbs (1996) suggested that all lexical items have collocations; and Hoey (2004) accommodated collocation within a model of 'lexical priming,' suggesting that most sentences are made

comparative linguistics. Independently of the German linguistic movements, Collitz became a strong advocate of the American philologies, which were widely ignored in Europe.

Hermann Collitz was honored in a *festschrift* (*Studies in honor of Hermann Collitz*, 1930) and – after his death – in several obituaries that cited his long list of works on Indo-European linguistics and especially the history of German, English, the other Germanic languages, and also Greek and Latin (cf. Historical Use of the Term Collocation

The fact that certain words co-occurred frequently was noticed in Biblical concordances (e.g., Cruden listed the occurrences of *dry* with *ground* in 1769). Style and usage guides in the 19th and 20th centuries (e.g., Fowler's *The King's English*) addressed only the overuse of collocations, labeling them clichés and criticizing their use, especially by journalists (e.g., Myles na Gopaleen (see O'Nolan, 1977: 225–6), in a more humorous vein: 'When and again have I asked you not to do that? Time ... What is our civilization much? Vaunted. What is the public? Gullible. What interests? Vested.').

Collocation in Modern Linguistics

In modern linguistics, collocation refers to the fact that certain lexical items tend to co-occur more frequently in natural language use than syntax and semantics alone would dictate. Collocation was first given theoretical prominence by J. R. Firth, who separated it from cognitive and semantic ideas of word meaning, calling it an "abstraction at the syntagmatic level" (Firth 1957a: 196), and accorded it a distinct status in his account of the linguistic levels at which meaning can arise. Firth implicitly indicated that collocation required a quantitative basis, giving actual numbers of co-occurrences in some texts.

Halliday (1976) saw collocation as a cohesive device and identified the need for a measure of significant proximity between collocating items and said that collocation could only be discussed in terms of probability, thus validating the need for quantitative analyses and the use of statistics. Sinclair (Sinclair *et al.*, 1970) performed the first computational investigation of collocation, comparing written and spoken corpora, identifying ± five words as the span of significant proximity and experimenting with statistical measures and lemmatization.

Halliday (1966) and Sinclair (1966) thought that collocation could enable a lexical analysis of language independent of grammar. Sinclair (1991) suggested that lexical items could be defined by their collocational environments, saw collocation as part of the idiom principle (lexically determined choices), as opposed to the open choice principle (grammatically determined choices). Leech (1974: 20) included 'collocative' in his categories of meaning, but marginalized it as an idiosyncratic property of individual words, incapable of contributing to generalizations. Sinclair (1987c) and Stubbs (1996) suggested that all lexical items have collocations; and Hoey (2004) accommodated collocation within a model of 'lexical priming,' suggesting that most sentences are made

up of interlocking collocations, and can therefore be seen as reproductions of earlier sentences.

Collocation and Lexicography

The pedagogical value of collocation was recognized by English teachers in the 1930s. English collocations were described in detail by Harold Palmer in a report on phraseology research with A. S. Hornby, using the term fairly loosely to cover longer phrases, proverbs, and so on, as well as individual word combinations. Palmer and Hornby showed a major interest in the classification of collocations in grammatical and semantic terms but also used collocations to indicate the relevant senses of words in word lists (**draw** 1. e.g., *a* ***picture*** 2. e.g., *a* ***line***), and in their dictionary examples (a practice continued in Hornby's (1948) and subsequent editions of the *Oxford advanced learner's dictionary*).

Early EFL dictionaries avoided using the term collocation, e.g., Hornby (1974) referred to "special uses of an adjective with a preposition" (**liable***: ~for, be ~ to sth*), and a "special grammatical way in which the headword is used" (**meantime***: in the ~*). Proctor (1978), in the *Longman dictionary of contemporary English*, referred to "ways in which English words are used together, whether loosely bound or occurring in fixed phrases" and "special phrases in which a word is usually (or always) found"; however, the dictionary also had a section headed 'Collocations,' defined as "a group of words which are often used together to form a natural-sounding combination," and stated that they are shown in three ways: in example sentences, in explanations in Usage Notes, or in heavy black type inside round brackets if they are very frequent or almost a fixed phrase ("but not an idiom"). These are signaled by 'in the phr.' or similar rubrics, and Procter (1978) gave the example *a mountain fastness*.

Later EFL dictionaries (*Cobuild*, *Cambridge*, *Macmillan*, etc.) continued to incorporate collocations in their dictionaries, including them in definitions and examples and typographically highlighting them in phrases. Sinclair's Introduction to the *Cobuild dictionary* (1987b), in the section on 'Word and Environment,' speaks of "the way in which the patterns of words with each other are related to the meanings and uses of the words" and says that "the sense of a word is bound up with a particular usage ... a close association of words or a grouping of words into a set phrase" and "(a word) only has a particular meaning when it is in a particular environment." Examples such as *hard luck, hard facts, hard evidence, strong evidence, tough luck,* and *sad facts* are discussed.

In Sinclair (1987b), collocates are defined as "words which co-occur significantly with headwords," and regular or significant collocation as "lexical items occurring within five words ... of the headword" with a greater frequency than expected, which "was established only on the basis of corpus evidence." For the first time in lexicography, a statistical notion of collocation had been introduced.

Collocation is used to distinguish senses: "Different sets of collocates found with these different senses pinpoint the fact that they *are* different senses"; "Collocation ... frequently reinforces meaning distinctions"; and lexical sets used in disambiguation are "signalled by coincidence of collocation" (Sinclair, 1987a). Collocation can also be a marker of metaphoricity: the presence of modifiers and qualifiers indicates metaphorical uses of *treadmill* and *blanket*, e.g., ... *the* ***corporate*** *treadmill; ... the treadmill* ***of office life***; *a* ***security*** *blanket* ***for new democracies***; *a blanket* ***of snow*** (ibid). Collocation is the "lexical realisation of the situational context" (ibid.). In the central patterns of English, "meaning was only created by choosing two or more words simultaneously" (ibid.). However, the flexibility of collocation (sometimes crossing sentence boundaries) can cause problems in the wording of definitions: often, "no particular group of collocates occurs in a structured relationship with the word" and therefore "there is no suitable pattern ready for use as a vehicle of explanation" (ibid.). The difficulty of eliciting collocates by intuition is discussed; we tend to think of semantic sets: *feet* suggests "*legs, toes, head* or *shoe, sandals, sock*, or *walk, run*," whereas significant corpus collocates of *feet* are "*tall, high, long*, and numbers" (ibid.). Prompted by *hint,* we produce "*subtle, small, clue*"; the corpus indicates "*give, take, no*." The difference between left-hand and right-hand collocates is exemplified by *open*: the most frequent words before *open* are "*the, to, an, is, an, wide, was, door, more, eyes*" and after *open* are "*to, and, the, for, up, space, a, it, in, door*" (ibid.).

Lexicographers can also use collocations to distinguish between near-synonyms, e.g., the difference between *electric* (collocates: specific devices such as *guitar*, *chair*, *light*, *car*, *motor*, *windows*, *oven*, all 'powered by electricity'), and *electrical* (collocates: more generic terms such as *engineering, equipment, goods, appliances, power, activity, signals, systems*, etc., 'concerning or involving electricity').

Finding Collocations in a Corpus

Initially, collocates for dictionary headwords were identified manually by lexicographers wading through pages of printouts of concordance lines. This was

clearly unsatisfactory, and only impressionistic views were feasible. Right-sorted concordances obscured left-context collocates and vice versa. The fixed-length context of printouts prevented the observation of collocates beyond a few words.

Subsequent software developments have enabled the automatic measurement of statistically significant co-occurrences. These are within a specifiable and adjustable span or window of context, using different measures of statistical significance, principally mutual information (or MI-score) and t-score. MI-score privileges lower-frequency, high-attraction collocates (e.g., *dentist* with *hygienist*, *optician*, and *molar*) while t-score favors higher-frequency collocates (e.g., *dentist* with *chair*), including significant grammatical words (e.g., *dentist* with *a,* and *your*). The software can also display the collocate's positional distribution if required, and recursive options are available to investigate the detailed phraseology of collocating items.

Software has also become more publicly available, from *MicroConcord* to *Wordsmith Tools* and *Collocate*. Kilgarriff and Tugwell's *WordSketch* (Kilgarriff *et al.,* 2004) was used in creating the *Macmillan English dictionary* (Rundell, 2002) and offers clause-functional information about collocations, e.g., ***wear*** + objects: *suit, dress, hat*, etc. + prepositional phrases (after *of*: *armor, clothing, jeans*, etc.; after *with*: *pride, sleeve, collar,* etc.; after *on*: *sleeve, wrist, finger*, etc.; after *over*: *shirt, head, dress*, etc.); similarly, ***fish*** is the subject of the verbs *swim, catch, fry*, etc.; the object of the verbs *catch, eat, feed*, etc. and modified by the adjectives *tropical, bony, oily*, and so on.

Lexicographers are in general less concerned about the detailed classification of collocations, although their judgments affect the both the placement and specific treatment of the combinations. Hornby's attempts (e.g., Hornby, 1948, 1974) at classification (focusing on verbs) later used transformations and meaning distinctions as well as surface patterns, and Hunston and Francis (2000) listed the linguistic and lexicological terminology that has developed subsequently for collocational units: lexical phrases, composites, gambits, routine formulae, phrasemes, etc., and referred to the work of Moon (e.g. 1998) and Mel'čuk (e.g. 1998) in discussing degrees of fixity and variation, which does impact on lexicography.

However, one of Firth's (1957b) original terms, 'colligation,' used to describe the habitual co-occurrence of grammatical elements, has not achieved the same widespread usage as 'collocation.' One manifestation of colligation, phrasal verbs, the combination of verb and particle (adverb or preposition) to form semantic units, has been highlighted in EFL dictionaries. Several EFL publishers have produced separate dictionaries of phrasal verbs.

There have been some dictionaries of collocations, but so far each has had its own limitations: not wholly corpus-based (e.g., Benson *et al.*, 1986; Hill and Lewis, 1997), based on a small corpus (e.g., Kjellmer, 1994), or limited coverage (the recent *Oxford collocations dictionary for students of English* (Lea, 2002)).

Collocation in Computational Linguistics, Pedagogy, and Translation

Interest in collocation has increased substantially in the past decade, as evidenced by workshops at lexicographical, linguistic, pedagogical, and translation conferences. For computational purposes, the relevant features of collocation are that they are "arbitrary, domain independent, recurrent, and cohesive lexical clusters" (Smadja, 1993), and "of limited semantic compositionality" (Manning and Schütze, 1999).

But the greatest interest has been generated in the language-teaching profession, with numerous conference and journal papers. Lewis (2000) encapsulates the main concerns: students do not recognize collocations in their input, and hence fail to produce them; collocation represents fluency (which precedes accuracy, represented by grammar); transparent versus 'arbitrary' (or idiomatic) combinations, with familiar words in rarer combinations (a *heavy smoker* is not a fat person); transformation can be misleading (*extremely disappointed* but rarely *extreme disappointment*); students may generalize more easily from corpus concordance examples than from canonical versions in dictionaries (exploring versus explaining); collocation as a bridge between the artificial separation of lexis and grammar; collocation extends knowledge of familiar words (easier than acquiring new words in isolation); and longer chunks are more useful and easier to store than isolated words.

Conclusions and the Future

For many fields, it seems that collocation has a great future. The applications of collocation in language teaching have been one of the notable recent successes. Its more detailed exploration in large language corpora requires a significant advance in software. The exact parameters are not fully established, and the statistical measures can be improved. Research to identify word-senses by the clustering of collocates was initiated in the 1960s (Sinclair *et al.*, 1970), but has still not become sufficiently robust for automatic processing. The identification of lexical sets by collocation, signaled in Sinclair (1966; Sinclair *et al.*,

1970) and Halliday (1966), is yet to be achieved, as is a corpus-generated thesaurus. The theoretical impetus of collocation has yet to reach the level of a language-pervasive system, although Hoey's notion of Lexical Priming heads in that direction.
